Abstract. We propose an effective and complete method for verifying safety and liveness properties of timed systems, which is based on predicate abstraction for computing finite abstractions of timed automata and TCTL formulas, finite-state CTL model checking, and successive refinement of finite-state abstractions. Starting with some coarse abstraction of the given timed automaton and the TCTL formula we define a finite sequence of refined abstractions that converges to the region graph of the real-time system. In each step, new abstraction predicates are selected nondeterministically from a finite, predetermined basis. Symbolic counterexamples from failed model-checking attempts are used to heuristically choose a small set of new abstraction predicates for incrementally refining the current abstraction. Without sacrificing completeness, this algorithm usually does not require computing the complete region graph to decide model-checking problems. Abstraction refinement terminates quickly, as a multitude of spurious counterexamples is eliminated in every refinement step through the use of symbolic counterexamples for TCTL.

1 Introduction

Timed Automata [2] are state-transition graphs augmented with a finite set of real-valued clocks. The clocks proceed at a uniform rate and constrain the times at which transitions may occur. Given a timed automaton and a property expressed in a (timed) temporal logic, model checking answers the question whether the timed automaton satisfies the given formula. The fundamental graph-theoretic model checking algorithm by Alur, Courcoubetis and Dill [1] constructs a finite quotient, the so-called region graph, of the infinite state graph corresponding to the timed automaton. Algorithms directly based on the explicit construction of such a partition of states are inefficient since the number of equivalence classes of states of the region graph grows exponentially with the largest time constant and the number of clocks that are used to specify timing constraints.

In [18,17] we propose a novel method for verifying safety and liveness properties of timed systems based on predicate abstraction [13] for timed automata, finite-state model checking, and counterexample-guided abstraction refinement. We define a set of

** Currently at Stanford University. This research has been mainly conducted while the author was visiting SRI International.
so-called *basis predicates*, which are expressive enough for distinguishing between any two clock regions. This set of predicates determines a strongly preserving abstraction in the sense that a timed automaton validates a \( \mu \)-calculus formula if the corresponding finite abstraction validates this formula. The control structure of the timed automaton is preserved in the abstract system. The abstracted systems no longer refer to the real-time nature of computations, and finite-state model checkers can be used to establish safety and liveness properties in the abstracted system.

In many cases it is not necessary to compute the exact abstraction using the entire basis of predicates, since a coarser approximation of this is sufficient for proving or refuting the desired property. Since we consider safety and liveness properties we maintain both under- and over-approximations of the given timed system. These approximations are computed via an iterative abstraction-refinement process that starts with some coarse approximations of the timed system and computes a sequence of approximations until the one necessary for proving or refuting the property is obtained. In each refinement step new abstraction predicates are selected from the finite set of basis predicates and new, more detailed approximations are computed. Hereby, the choice of predicates is guided by counterexamples from failing model-checking attempts. We call this method *lazy approximation*. This process of abstracting and refining approximations is illustrated in Figure 1. When using the entire basis of predicates for computing the approximations, the under- and over-approximation are identical, yielding therefore a strongly property preserving abstraction of the timed system. Since the sequence of approximations converges toward the region graph of the real-time systems, the method of lazy approximation is complete [18,17]. The main advantage of this approach is that finite time-abstractions are computed lazily. This results in substantial savings in computation whenever coarse abstractions are sufficient to prove the property at hand. Standard benchmark examples for timed automata such as train gate controller and a
version of Fischer’s mutual exclusion protocol can be proved using only a few abstraction predicates.

In this paper we extend our previous results [18,17] in several directions. First, we consider TCTL [1] for expressing qualitative and quantitative properties of timed systems, instead of the untimed logic considered in [18,17]. We define an abstraction function for TCTL that maps a TCTL formula to a CTL formula, together with the inverse operation of concretization. The predicates necessary for the abstraction are extracted from the timed-bounded modalities of the TCTL formula. For extracting the predicates we introduce for every timed-bounded modality of a given TCTL formula $\varphi$ a new clock variable $z_i$. Now, the set of abstraction predicates $P_\varphi$ with respect to $\varphi$ consists of all the formulas $z_i \sim c$ with free variables $z_i$, where $\sim c$ denotes the timed bound of the modalities occurring in $\varphi$. For examples, the abstraction predicates corresponding to the
TCTL formula $\varphi = \mathbf{EG}_{c_2} p \land A[q U_{\leq 4} r]$, with $p$, $q$, $r$ atomic propositions, are given as $\psi_1 \equiv z_1 < 2$, $\psi_2 \equiv z_2 \leq 4$. The resulting abstract CTL formula is now obtained using these predicates as $\varphi^A = \mathbf{EG}(p \land \psi_1) \land A[q U (r \land \psi_2)]$.

Second, in contrast to the previous version of our algorithm [18,17], where refined approximations are recomputed from scratch, we compute abstraction refinements in an incremental fashion, following the approach outlined by Das and Dill [8] for the untimed case.

Third, we introduce a symbolic form of counterexamples for the full TCTL logic, as sequences over sets of states. These symbolic structures are timed extensions of the symbolic counterexamples for (untimed) CTL [20]. We use symbolic counterexamples in the abstraction-refinement algorithm as a heuristic for selecting new abstraction predicates from the given set of basis predicates. Symbolic counterexamples make the refinement process converge more quickly compared to the use of linear counterexamples, as a multitude of spurious counterexamples are discarded in every refinement step. Moreover, since we define symbolic counterexamples for the full TCTL, the method of lazy approximation is applicable for full TCTL, and not only for a fragment of universal formulas as it is the case when using linear counterexamples.

The main contributions of our paper are

1. A definition of abstraction functions for timed automata and TCTL based on predicate abstraction.
2. A definition of symbolic counterexamples for full TCTL.
3. An incremental abstraction refinement algorithm for computing finite approximations of timed automata and TCTL formulas.
4. A proof for termination, soundness and completeness of the abstraction refinement algorithm.

Related Work. The abstract interpretation framework [7] has been used earlier in the context of real-time systems for formalizing approximations of safety properties [23,11,9]. In contrast, the techniques proposed in [18,17] and extended in this paper, also allow for verifying liveness. Whereas verification techniques for infinite-state systems based on predicate abstraction [13,5,19,14] are usually used in an incomplete way for proving safety properties, our verification method for timed systems is even complete for liveness properties.
Counterexample-guided refinement has been studied by many researchers, and recent work includes [6,8,15,14]. In contrast to these approaches, we use counterexamples only as a heuristic for selecting good pivot predicates from a fixed, predetermined pool of abstraction predicates to speed convergence of the approximation processes.

Dill and Wong-Toi [11] also use an iteration of both over- and under-approximations of the reachable state set of timed automata, but their techniques are limited to proving invariants. Daws and Tripakis [9] propose several abstractions that reduce the state space of a timed system, while preserving reachability properties. Tripakis and Yovine [22] show how to abstract dense real time to obtain time-abstracting, finite bisimulations. Behrmann, Bouyer, Larsen and Pelánek [4] propose zone based abstractions with respect to the minimal and maximal constants to which clocks are compared, obtaining a sound and complete verification method for reachability. Whenever it suffices to compute rather coarse abstractions, we expect to obtain much smaller transition systems by means of lazy approximation. Alur, Itai, Kurshan, and Yannakakis [3] present a technique based on over-approximations: the method consists in attempting to prove a property on an abstract system, where some clocks are ignored; if this attempt fails, clocks are reintroduced progressively until either the property is proved on the abstract system, or all the clocks have been reintroduced. The method still requires exact computation of the region graph for each abstracted system.

Henzinger, Jhala, Majumdar, and Sutre [14] present an abstraction-refinement algorithm for model checking safety properties that integrates the construction of the abstract model with the verification process. The abstract model is constructed on demand during verification, by refining only parts of the current abstract model. However, this method allows for checking only reachability properties, whereas our approach can be used to verify or refute any kind of TCTL properties.

All the above-described approaches use linear counterexamples during the refinement process. In contrast, symbolic counterexamples make the refinement process converge more quickly compared to the use of linear counterexamples, since several spurious counterexamples are discarded in one refinement step.

Organization. The remainder of this paper is organized as follows. Section 2 reviews the basic notions of timed automata and TCTL. Finite over- and under-approximations of timed automata are defined in the first part of Section 3, while the second part contains definitions of abstraction and concretization functions for TCTL. Symbolic counterexamples for TCTL as sequences over sets of states are introduced in Section 4. In Section 5, we define the iterative abstraction refinement algorithm and show termination and completeness thereof. Finally, Section 6 contains some concluding remarks. For lack of space we omit some of the proofs, but detailed proofs can be found in [18,21].

2 Preliminaries

Given a set of clocks $C$, the set of timing (or clock) constraints $\text{Constr}$ comprises $\text{tt}$, $x \gg d$, and $x - y \gg d$, where $x, y \in C$, $d \in \mathbb{N}$, $\gg \in \{\leq, <, =, >, \geq\}$. The set $\text{Inv}$ is the subset of $\text{Constr}$, where $\gg$ is chosen from $\{\leq, <\}$. For a positive integer $\gamma$, $\text{Constr}(\gamma)$ is the finite subset of all clock constraints $x \sim \gamma$, $x - y \sim \gamma$, where $x, y \in C$.

A timed automaton [2] is a tuple $S = \langle L, P, C, E, Lo, I \rangle$, where
\(- L \) is a nonempty finite set of locations.
\(- P : L \rightarrow \mathcal{P}(AP)\) maps each location to a set of propositional symbols \(AP\).
\(- C \) is a finite set of clocks.
\(- E \subseteq L \times \mathcal{P}(\text{Constr}) \times \mathcal{P}(C) \times L \) is a transition relation; we write \(l \xrightarrow{\mathcal{E},r} l'\) for \((l, g, r, l') \in E\).
\(- L_0 \subseteq L \) is the set of initial locations.
\(- I : L \rightarrow \mathcal{P}(\text{Inv})\) assigns a set of downward closed clock constraints to each location \(l\); the elements of \(I(l)\) are the \textit{invariants} for location \(l\).

A function \(\nu : C \rightarrow \mathbb{R}_{\geq 0}\) is a \textit{clock valuation}, and the set of clock valuations is collected in \(\mathcal{V}_C\). \(\mathcal{V}_0\) denotes the set of initial clock valuations that assigns to every clock the value 0. The clock valuation \((\nu + \delta)\) is obtained by adding \(\delta\) to the value of each clock in \(\nu\). For \(X \subseteq C\), \(\nu[X := 0]\) denotes the clock valuation that updates every clock \(x \in X\) to zero, and leaves all the other clock values unchanged. The value \(g\nu\) of a clock constraint \(g\) with respect to the clock valuation \(\nu\) is obtained by substituting the clocks \(x\) in \(g\) with the corresponding value \(\nu(x)\). If \(g\nu\) simplifies to the true value, \(\nu\) satisfies \(g\) and we write \(\nu \models g\). A set \(X \subseteq \mathcal{V}_C\) of clock valuations satisfies \(g \in \text{Constr}\), written as \(X \models g\), if and only if \(\forall \nu \in X : \nu \models g\). A pair \((l, \nu) \in L \times \mathcal{V}_C\) is called a \textit{timed configuration}, if it satisfies the invariants \(I(l)\); formally, \(\nu \models I(l)\) iff \(\forall g \in I(l) : \nu \models g\).

A \textit{clock region} [2] is a set \(X \subseteq \mathcal{V}_C\) of clock valuations, such that for all timing constraints \(g \in \text{Constr}(\gamma)\) and any two \(\nu_1, \nu_2 \in X\) it is the case that \(\nu_1 \models g\) if and only if \(\nu_2 \models g\). In this case we write \(\nu_1 \equiv \nu_2\).

A \textit{timed step} is either a \textit{delay step}, where time advances by some positive real-valued \(\delta\), or an instantaneous \textit{state transition step}. For \(\delta > 0\), we say that the timed configuration \((l, \nu + \delta)\) is obtained from \((l, \nu)\) by a \textit{delay step} \((l, \nu) \xrightarrow{\delta} (l, \nu + \delta)\), if the invariant constraint \(\nu + \delta \models I(l)\) holds. A \textit{state transition step} \((l, \nu) \xrightarrow{\gamma} (l', \nu')\) occurs if there exists a \(l \xrightarrow{\mathcal{E},r} l' \in E\), and \(\nu \models g, \nu' := \nu[r := 0]\), and \(\nu' \models I(l')\).

The lazy approximation method, we present here, allows for verifying not only safety properties, but also liveness properties. Liveness in dense real time is complicated by the possible sequences of infinitesimally decreasing delay steps; they constitute a degenerated behavior of a system, a behavior that has to be disallowed. As in [18,17], we eliminate this undesired behavior by restricting the model of timed automata to delay steps that force a clock to step beyond integer bounds when all fractional clock values are not zero. We have shown [18,17] that such a restriction does not change the possible observations of the model with respect to \(\mu\)-calculus formulas. The proof can easily be adapted to TCTL formulas.

A \textit{restricted delay step} [18,17] is a delay step \((l, \nu) \xrightarrow{\delta} (l, \nu + \delta)\) for all positive, real-valued \(\delta\), such that

\[\exists x \in C. \exists k \in \{0, \ldots, \gamma\}. \nu(x) = k \lor (\nu(x) < k \land \nu(x) + \delta \geq k).\]

In this paper we consider timed systems with restricted delay steps. The union of restricted delay and state transition steps defines the timed transition relation \(\Rightarrow\) of a timed system \(S\).

The semantics of a timed system \(S = \langle L, L_0, C, I, P, E \rangle\) is given by associated with it a transition system \(M = \langle S, S_0, P, N \rangle\), where \(S = L \times \mathcal{V}_C\), \(S_0 = L_0 \times \mathcal{V}_0 \subseteq S\) are
Similarly to timing constraints, the value of an abstraction predicate \( \psi \) is denoted by the juxtaposition \( l(\nu) \). Whenever the abstraction predicate \( \psi \) evaluates to true, we write \( \nu \models \psi \).

A set of abstraction predicates \( \mathcal{P} = \{ \psi_0, \ldots, \psi_{n-1} \} \) determines an abstraction function \( \alpha \), which maps clock valuations \( \nu \) to a bitvector \( b \) of length \( n \), such that the \( i \)-th component of \( b \) is set if and only if \( \psi_i \) holds for \( \nu \). Here, we assume that bitvectors of length \( n \) are elements of the set \( \mathcal{B}_n \), which are functions of domain \( \{0, \ldots, n-1\} \) and codomain \( \{0, 1\} \). The inverse image of \( \alpha \), that is, the concretization function \( \gamma \), maps a bitvector to the set of clock valuations that satisfy all \( \psi_i \) whenever the \( i \)-th component of the bitvector is set. Thus, a set of concrete states \( (l, \nu) \) is transformed by the abstraction function \( \alpha \) into the abstract state \( \alpha(l, \nu) \), and an abstract state \( (l, b) \) is mapped by \( \gamma \) to a set of concrete states \( \gamma(l, b) \).

**Definition 1 (Abstraction Predicates [18,17]).** Given a set of clocks \( C \), an abstraction predicate with respect to \( C \) is any formula with the set of free variables in \( C \). Similarly to timing constraints, the value of an abstraction predicate \( \psi \) with respect to a clock valuation \( \nu \), where both free and bound variables are interpreted in the domain \( C \), is denoted by the juxtaposition \( \nu \models \psi \).

The semantics of TCTL formulas is given in the usual way, with respect to a transition system. The notions of s-path and TCTL-structure are as in [1], and are reviewed in Appendix A.

### 3 Abstraction Functions

#### 3.1 Abstracting Timed Systems

**Definition 2 (Abstraction/Concretization [18,17]).** Let \( C \) be a set of clocks and \( \mathcal{V}_C \) the corresponding set of clock valuations. Given a finite set of predicates \( \mathcal{P} = \{ \psi_0, \ldots, \psi_{n-1} \} \), the abstraction function \( \alpha : L \times \mathcal{V}_C \to L \times \mathcal{B}_n \) is defined by

\[
\alpha(l, \nu)(i) := (l, \psi_i) \nu
\]
and the concretization function $\gamma : L \times B_n \to L \times \mathcal{P}(\mathcal{V}_c)$ is defined by

$$\gamma(l, b) := \{(l, v) \in L \times \mathcal{V}_c \mid I(l) \land \bigwedge_{i=0}^{n-1} \psi_i \in b(i)\}.$$ 

We also use the notations $\alpha(S) := \{\alpha(l, v) \mid (l, v) \in S\}$ and $\gamma(S^a) := \{\gamma(l, b) \mid (l, b) \in S^a\}$. Now, the abstraction/concretization pair $(\alpha, \gamma)$ forms a Galois connection.

**Definition 3 (Feasible State).** An abstract state $(l, b)$ is feasible if and only if its concretization is not empty, that is, $\gamma(l, b) \neq \emptyset$.

A set of predicates is feasible, if the conjunction of the predicates is satisfiable.

**Definition 4 (Over-/Under-approximation [18,17]).** Given a (concrete) transition system $M = (S', S_0', P, \Rightarrow)$, where $S' = L \times \mathcal{V}_C$, $S_0' = L_0 \times \mathcal{V}_0$, and a set $\Psi$ of abstraction predicates, we construct two (abstract) transition systems $M^+_\Psi = (S^a, S_0^a, P, \Rightarrow^+)$, and $M^-_\Psi = (S^a, S_0^a, P, \Rightarrow^-)$.

- $S^a := L \times B_n$
- $(l, b)\Rightarrow^+(l', b')$ iff $\exists \nu, \nu' \in \mathcal{V}_C$ s.t. $(l, \nu) \in \gamma(l, b) \land (l', \nu') \in \gamma(l', b')$. $(l, \nu)\Rightarrow(l', \nu')$
- $(l, b)\Rightarrow^-(l', b')$ iff $(l, b)$ feasible, and $\forall \nu \in \mathcal{V}_C$ s.t. $(l, \nu) \in \gamma(l, b)$. $\exists \nu' \in \mathcal{V}_C$ s.t. $(l', \nu') \in \gamma(l', b')$. $(l, \nu)\Rightarrow(l', \nu')$
- $S_0^a := \{(l_0, b_0) \mid l_0 \in L_0$, and $b_0(i) = 1$ iff $v_0 \models \phi_i\}$.

$M^+_\Psi$ is called an over-approximation, and $M^-_\Psi$ an under-approximation of $M$.

Obviously, we have that $\Rightarrow^\pm \subseteq \Rightarrow^\pm$. If the set $\Psi$ of abstraction predicates is understood from the context, we omit it in the notation for under-, and over-approximation, and we write $M^\pm$, respectively $M^\pm$.

For the transition relations $\Rightarrow^\pm$, $\Rightarrow^\pm$, and $\Rightarrow$ we define $\gamma(\Rightarrow^\pm)$, $\gamma(\Rightarrow^\pm)$, respectively $\alpha(\Rightarrow)$ as follows:

$$\gamma(\Rightarrow^-) := \{((l, \nu), (l', \nu')) \in S^- \mid \exists b, b'. (l, b) \Rightarrow^- (l', b') \land (l, \nu) \in \gamma(l, b) \land (l', \nu') \in \gamma(l', b')\}$$

$$\gamma(\Rightarrow^+) := \{((l, \nu), (l', \nu')) \in S^+ \mid \exists b, b'. (l, b) \Rightarrow^+ (l', b') \land (l, \nu) \in \gamma(l, b) \land (l', \nu') \in \gamma(l', b')\}$$

$$\alpha(\Rightarrow) := \{((l, \nu), \alpha(l', \nu')) \mid (l, \nu) \Rightarrow (l', \nu')\}$$

The next statement follows directly from Definition 4.

**Lemma 1 (18,17).** For a (concrete) transition system $M$ with the transition relation $\Rightarrow$ and the corresponding over- and under-approximations $M^+_\Psi$, $M^-_\Psi$ with respective transition relations $\Rightarrow^+$, and $\Rightarrow^- : (1) \gamma(\Rightarrow^-) \subseteq \subseteq \gamma(\Rightarrow^+)$ and (2) $\Rightarrow^- \subseteq \alpha(\Rightarrow) \subseteq \Rightarrow^+$. 
Definition 4 does not allow the incremental computation of over- and under-approximations. When adding new predicates to \( \mathcal{P} \), new approximations have to be constructed from scratch starting from the initial transition system. We modify Definition 4 such that successive approximations can be computed incrementally from previously obtained approximations by adding new predicates from the basis.

We introduce the following notations. A bitvector of length \( k \) is denoted by \( b[0 : k - 1] \), and corresponds to the set \( \mathcal{P}_k = \{ \psi_0, \ldots, \psi_{k-1} \} \) of abstraction predicates. The abstraction and concretization functions determined by \( \mathcal{P}_k \) are denoted by \( \alpha_k, \gamma_k \), respectively. The finite over-approximation of \( \mathcal{M} \) with respect to \( \mathcal{P}_k \) is denoted by \( \mathcal{M}_{\mathcal{P}_k}^+ \) and is the tuple \( \langle S_k^+, S_0^+, \mathcal{P}, \Rightarrow^+ \rangle \). Similarly, the finite under-approximation of \( \mathcal{M} \) with respect to \( \mathcal{P}_k \) is denoted by \( \mathcal{M}_{\mathcal{P}_k}^- \) = \( \langle S_k^-, S_0^-, \mathcal{P}, \Rightarrow^- \rangle \). Note that the mapping function \( \mathcal{P} \) does not depend on the abstraction predicates, merely on the finite control structure \( L \).

**Definition 5 (Incremental Over-/Under-approximation).** For a timed system \( S \), with corresponding transition system \( \mathcal{M} \), and a TCTL formula \( \varphi \), let \( \mathcal{P} \) be the corresponding basis of abstraction predicates, \( \mathcal{M}_{\mathcal{P}_k}^+ = \langle S_k^+, S_0^+, \mathcal{P}, \Rightarrow^+ \rangle \) and \( \mathcal{M}_{\mathcal{P}_k}^- = \langle S_k^-, S_0^-, \mathcal{P}, \Rightarrow^- \rangle \) the over-approximation and under-approximation of \( \mathcal{M} \) obtained in step \( i \) with respect to a set \( \mathcal{P}_k \subset \mathcal{P} \) of abstraction predicates, respectively. Let \( \mathcal{P}_c \) be the set of predicates obtained from the failed model-checking attempt in step \( i \). The over-approximation \( \mathcal{M}_{\mathcal{P}_{ci}}^+ = \langle S_{ci}^+, S_{0ci}^+, \mathcal{P}, \Rightarrow_c^+ \rangle \) respectively under-approximation \( \mathcal{M}_{\mathcal{P}_{ci}}^- = \langle S_{ci}^-, S_{0ci}^-, \mathcal{P}, \Rightarrow_c^- \rangle \) obtained in step \( i + 1 \) with respect to the set of predicates \( \mathcal{P}_{ci} = \mathcal{P}_k \cup \mathcal{P}_c \), is derived from \( \mathcal{M}_{\mathcal{P}_k}^+ \), respectively \( \mathcal{M}_{\mathcal{P}_k}^- \), as follows:

- \( S_{ci}^+ = \{(l, b[0 : m - 1]) \mid (l, b[0 : k - 1]) \in S_k^+ \text{ and } \forall i = k, \ldots, k + k' - 1. b[i] = 1 \text{ if } \mathcal{P}_k \cap \psi_i \neq \emptyset, \text{ else } b[i] = 0\} \)
- \( (l, b[0 : m - 1]) \Rightarrow_m^+(l', b'[0 : m - 1]) \text{ iff } \)
  - \( (l, b[0 : k - 1]) \Rightarrow_c^+(l', b'[0 : k - 1]) \text{ and } \)
  - \( \exists \nu_m, \nu'_m \in \mathcal{V}_C \text{ s.t. } (l, \nu_m) \in \gamma_m(l, b[0 : m - 1]) \text{ and } (l', \nu'_m) \in \gamma_m(l, b'[0 : m - 1]) \text{ with } \nu_m = \nu_c \cap \{v \in \mathcal{V}_C \mid \mathcal{P}_k \nu \equiv 1\} \text{ and } \nu'_m = \nu'_c \cap \{v' \in \mathcal{V}_C \mid \mathcal{P}_k \nu \equiv 1\} \text{ such that } (l, \nu_m) \Rightarrow_c(l', \nu'_m). \)
- \( (l, b[0 : m - 1]) \Rightarrow_c^-(l', b'[0 : m - 1]) \text{ iff } \)
  - \( (l, b[0 : k - 1]) \Rightarrow_c^-(l', b'[0 : k - 1]) \text{ and } \)
  - \( \forall \nu_m, \nu'_m \in \mathcal{V}_C \text{ s.t. } (l, \nu_m) \in \gamma_m(l, b[0 : m - 1]) \text{ and } (l', \nu'_m) \in \gamma_m(l', b'[0 : m - 1]) \text{ with } \nu_m = \nu_c \cap \{v \in \mathcal{V}_C \mid \mathcal{P}_k \nu \equiv 1\} \text{ and } \nu'_m = \nu'_c \cap \{v' \in \mathcal{V}_C \mid \mathcal{P}_k \nu \equiv 1\} \text{ such that } (l, \nu_m) \Rightarrow_c(l', \nu'_m). \)

The set \( S_{ci}^+ \) can also be defined as in Definition 4 as the product of \( L \) and \( B_m \), where \( B_m \) is the set of all bitvectors of length \( m \). However, the above definition is more restrictive, in the sense that a smaller set of abstract states than \( L \times B_m \) is obtained, since infeasible states are discarded.

### 3.2 TCTL Abstraction

We define abstractions and concretizations functions for TCTL formulas based on a set of abstraction predicates \( \mathcal{P}_{\varphi} \). The predicates are extracted from the timed-bounded modalities of the formulas. For every timed-bounded modality of a given formula \( \varphi \) we
introduce a new clock variable $z_i$. Now, the set of abstraction predicates $Ψ_ϕ$ with respect to $ϕ$ consists of all the formulas $z_i ∼ c_i$ with free variables $z_i$, where $∼ c_i$ denotes the timed bound of the modalities occurring in $ϕ$. For example, the abstraction predicates corresponding to the formula $ϕ = EG_{z_2} p \land A[q U_{z_4} r]$, with $p$, $q$, $r$ atomic propositions, are given as $Ψ_ϕ = \{z_1 < 2, z_2 \leq 4\}$.

**Definition 6 (TCTL Abstraction Predicates).** Given a TCTL formula $ϕ$. A TCTL abstraction predicate is a formula $z_i ∼ c_i$, with $z_i$ a free variable and $c_i$ the time bound of the $i$-th modality in $ϕ$. The TCTL abstraction predicates corresponding to a formula $ϕ$ are collected in the set $Ψ_ϕ$. If $ϕ$ does not contain any timed-bounded modalities, then $Ψ_ϕ$ is empty.

**Definition 7 (TCTL Abstraction/Concretization).** Given a TCTL formula $ϕ$, and a set $Ψ_ϕ$ of abstraction predicates. Furthermore, let $ψ \equiv z ∼ c$ be a predicate in $Ψ_ϕ$, corresponding to the bounded modality $U_{z ∼ c}$. The abstraction function $α_ϕ : TCTL \to CTL$ is defined inductively over the structure of $ϕ$.

$\alpha_ϕ(\tt) := \tt \quad \alpha_ϕ(p) := p \quad \alpha_ϕ(¬ϕ) := ¬\alpha_ϕ(ϕ) \quad \alpha_ϕ(ϕ_1 ∨ ϕ_2) := \alpha_ϕ(ϕ_1) ∨ \alpha_ϕ(ϕ_2) \quad \alpha_ϕ(E[ϕ_{1 ∼ c_1} U_{z ∼ c_2} ϕ_{1 ∼ c_1}]) := E[α_ϕ(ϕ_{1 ∼ c_1}) U (α_ϕ(ϕ_{1 ∼ c_1}) ∨ ψ_{1 ∼ c_1})] \quad \alpha_ϕ(A[ϕ_{1 ∼ c_1} U_{z ∼ c_2} ϕ_{1 ∼ c_1}]) := A[α_ϕ(ϕ_{1 ∼ c_1}) U (α_ϕ(ϕ_{1 ∼ c_1}) ∨ ψ_{1 ∼ c_1})]

The concretization function $γ_ϕ : CTL \to TCTL$ maps a CTL formula to a TCTL formula, and is the inverse operation to $α_ϕ$, that is $γ_ϕ(ϕ) = α_ϕ^{-1}(ϕ)$.

Now, given a timed automaton $S$ with a set of clocks $C$, and a TCTL formula $ϕ$, we add the clocks $z_i$ corresponding to the bounded modalities of $ϕ$ to $C$, and define the abstraction predicates with respect to the new set of clocks. The initial values of the clocks $z_i$ equal zero, and the largest constants, which these clocks are even compared to are given by the constants $c_i$, appearing in the bounded modalities of $ϕ$. Let $Ψ$ be the set of abstraction predicates corresponding to $S$ and $ϕ$. If $ϕ$ does not contain any timed-bounded modalities, then $Ψ$ consists only of the predicates with respect to the automaton clocks, as in Definition 1.

**Definition 8 (Predicate Abstracted Semantics of CTL).** Let $ϕ^c$ be a TCTL formula, $M = (S^c, S^c_0, P, ⇒)$ a transition system, and $Ψ$ a set of abstraction predicates. Consider, as given in Definition 4, the over-approximation $M^c_Ψ = (S^c, S^c_0, P, ⇒^c)$, and the under-approximation $M^f_Ψ = (S^f, S^f_0, P, ⇒^f)$ of $M$. Furthermore, let $ϕ = α_ϕ(ϕ^c)$ be the CTL formula obtained by abstracting $ϕ^c$ using the predicates corresponding to the bounded modalities in $ϕ$. Then, the predicate abstracted semantics $[ϕ]^M_Ψ$, where $σ$ is either $+$ or $−$, of the CTL formula $ϕ$ with respect to the finite-state transition systems $M^c_Ψ$ is defined in a mutually inductive way. The notation $σ^c$ is used to toggle the sign $σ$.

$\llbracket \tt \rrbracket^{M^c_Ψ} := S^c \quad \llbracket p \rrbracket^{M^c_Ψ} := \{(l, b) \in S^c | p \in P(l)\} \quad \llbracket ¬ϕ \rrbracket^{M^c_Ψ} := S^c \setminus \llbracket ϕ \rrbracket^{M^c_Ψ} \quad \llbracket p \rrbracket^{M^f_Ψ} := \{(l, b) \in S^f | p \in P(l)\} \quad \llbracket ¬ϕ \rrbracket^{M^f_Ψ} := S^f \setminus \llbracket ϕ \rrbracket^{M^f_Ψ}$
Let $\Psi$ be a set of abstraction predicates. Then $\Psi$ is a basis for $\mathcal{M}$ with respect to the TCTL logic, that is, the approximation is property-preserving.

Definition 9 (Basis [18,17]).

Let $\mathcal{S}$ be a timed automaton with clock set $C$ and let $\Psi$ be a set of abstraction predicates. Then $\Psi$ is a basis with respect to $\mathcal{S}$ iff for all clock valuations $v_1, v_2 \in \mathcal{V}_C$:  

\[
\forall \psi \in \Psi, v_1 \models \psi \Leftrightarrow v_2 \models \psi \Rightarrow v_1 \equiv v_2.
\]

For example, for a timed automaton $\mathcal{S}$ with clock set $C$ and largest constant $\gamma$ the (infinite) set of clock constraints $Constr$, the (infinite) set of invariant constraints $Inv$, the (finite) set of clock constraints $Constr(\gamma)$, and the (finite) set of membership predicates for the quotient $\mathcal{V}_C$ modulo $\equiv$ are all basis sets. Since the set of predicates $Constr(\gamma)$ is finite, there is a finite basis for every timed automaton. Notice, however, that this basis is not necessarily minimal.

Theorem 2. Let $\mathcal{S}$ be a timed automaton, $\mathcal{M}$ the corresponding transition system, and $\varphi$ a TCTL formula. Furthermore, let $C$ be the set of clocks corresponding to $\mathcal{S}$ and $\varphi$, and $\gamma$ the largest constant, which these clocks are compared to. Let $\Psi$ be a basis with respect to $\mathcal{S}$ and $\mathcal{M}$, $\mathcal{M}^\Psi$, $\mathcal{M}^\gamma$ the under- and over-approximation of $\mathcal{S}$ with respect to $\Psi$. Then, for any TCTL formula $\varphi$,

\[
\|\varphi\|_{\mathcal{M}^\gamma} = \|\varphi\|_{\mathcal{M}^\Psi}.
\]

Corollary 1 (Basis Completeness). Let $\mathcal{S} = (L, L_0, C, I, P, E)$ be a timed automaton, and $\mathcal{M}$ the corresponding transition system. Then for any TCTL formula $\varphi$, and initial state $l_0 \in L_0$ the following holds: ($\Psi$ is a basis for $\mathcal{S}$ and $\varphi$)

\[
(l_0, b_0) \in \|\varphi\|_{\mathcal{M}^\gamma} \iff (l_0, b_0) \in \|\varphi\|_{\mathcal{M}^\Psi} \iff (l_0, b_0) \in \|\varphi\|_{\mathcal{M}^\gamma}.
\]
4 Symbolic Counterexamples for TCTL

Given a Kripke structure $\mathcal{M}$, with $S_0$ initial states, and a TCTL formula $\varphi$, a symbolic counterexample carries a justification that $\mathcal{M}, S_0 \vDash \varphi$. When we write $\bar{X}$, we mean a list of elements of the form $[X_0, \ldots]$, and $\bar{X}^m$ implies that the list $\bar{X}$ is of length $m+1$, that is, of the form $[X_0, \ldots, X_m]$. We write $c \vdash \mathcal{M}, C \vDash \varphi$ to denote that $c$ is a counterexample, which demonstrates that for every state $s \in C$, $\mathcal{M}, s \vDash \varphi$.

For a transition system $\mathcal{M} = \langle S, S_0, P, N \rangle$, and a set $C \subseteq S$, let $\mathcal{O}_0$ denote the set of all $s$-paths starting in any state in $C \cap S_0$, defined as $\mathcal{O}_0 = \{ \rho \in f(s) | s \in C \cap S_0 \}$ and $\mathcal{O}_0(t)$ be those states that can be reached from any state in $C \cap S_0$ at time point $t$, $\mathcal{O}_0(t) = \{ s \in S | s = \rho(t) \text{ and } \rho \in \mathcal{O}_0 \}$. For a bounded modality with time bound $t \sim c$, let $\zeta \in \text{AP}$ be an atomic proposition that holds in a state $s$ if and only if $s \in \mathcal{O}_0(t)$.

**Definition 10 (Symbolic Counterexamples).** 2 Let $\mathcal{M} = \langle S, S_0, P, N \rangle$ be a transition system, where $S = L \times V_C, S_0 \subseteq S$, and $N$ is the transition relation. For a TCTL formula $\varphi$, and a set of states $C \subseteq S_0$, a symbolic counterexample $c$ justifying $\mathcal{M}, C \vDash \varphi$ has the form $\bar{X}$, and is defined as follow.

1. A counterexample $c \vdash \mathcal{M}, C \vDash \varphi$ is a list $c = \bar{X}$, such that $\exists C' \subseteq S$ with
   - (a) $\mathcal{M}, C' \vDash \varphi \land \zeta$,
   - (b) $X_0 \subseteq C'$,
   - (c) $X_{i+1} \subseteq X_i \cup \overline{pre}(N)(X_i)$, for $i < m$,
   - (d) $C = X_m$.

2. A counterexample $c \vdash \mathcal{M}, C \vDash \varphi$ is a list $c = \bar{X}$, such that $\exists C' \subseteq S$ with
   - (a) $\mathcal{M}, C' \vDash \varphi \land \zeta$,
   - (b) $X_0 \subseteq C'$,
   - (c) $X_{i+1} \subseteq X_i \cup \overline{pre}(N)(X_i)$, for $i < m$,
   - (d) $C = X_m$.

5 Incremental Abstraction-Refinement Algorithm

**Definition 11 (Set Inclusion w.r.t. Clock Valuations).** For two sets of states $S = \{ (l_1, v_1), \ldots, (l_m, v_m) \}$ and $S' = \{ (l'_1, v'_1), \ldots, (l'_n, v'_n) \}$, the set inclusion with respect to clock valuations relation $S \subseteq_{\nu} S'$ is defined as:

$S \subseteq_{\nu} S'$ iff $[n = m, \ l_i = l'_i, \text{ and } v_i \subseteq v'_i \text{, for all } 0 \leq i \leq m]$.

The abstraction-refinement algorithm is displayed in Figure 2. The variables $\Psi_n$ and $\Psi_a$ store the currently unused (new) and used (actual) abstraction predicates, respectively. Initially, $\Psi_n$ contains those predicates from the basis that correspond to the bounded modalities of $\varphi$, and possibly some predicates derived from the timing constraints of the automaton, and $\Psi_a$ contains the remaining predicates (lines (1)-(2)). First, it is checked if $s_0 \in \gamma(\llbracket \alpha_n(\varphi) \rrbracket_{M_F})$ by calling a finite-state CTL model checker.

---

1 A $s$-path through $S$ is a map $\rho$ from $\mathbb{R}_0$ to $S$, satisfying $\rho(0) = s$, for $s \in S$. $f$ is a map, which assigns to every $s \in S$ a set of $s$-paths through $S$ [1]. See also Appendix A.

2 For lack of space we define here only counterexamples for $\text{EG}_{\sim c} \varphi$ and $\text{AG}_{\sim c} \varphi$, but the full definition can be found in Appendix B.
Algorithm: abstract_and_refine
Input: M, S, s₀, N, ϕ, P
Output: answer to model checking query “M, s₀ |= ϕ?”

choose \( P' = \{ \psi_1, \ldots, \psi_c \} \) from \( P \); \hspace{1cm} (1)
\( \psi'_a := P \setminus P' \); \hspace{1cm} (2)
loop
if \( s_0 \in \gamma([\alpha_c(\varphi)]^M_{s_0}) \) then return true \hspace{1cm} (3)
else if \( s_0 \notin \gamma([\alpha_c(\varphi)]^M_{s_0}) \) then return false \hspace{1cm} (4)
else let \([X_0, X_1, \ldots, X_n] \) be a counterexample in \( M_{s_0} \) \hspace{1cm} (6)
if there exists \([X'_0, X'_1, \ldots, X'_n] \) s.t. \( X'_i \subseteq \gamma(X_i) \) for all \( 0 \leq i \leq n \) \hspace{1cm} (7)
and \([X'_0, X'_1, \ldots, X'_n] \) is counterexample in \( M \) \hspace{1cm} (8)
then return false \hspace{1cm} (9)

choose feasible \( \Psi' = \{ \psi_1, \ldots, \psi_c \} \subseteq \Psi_a \) s.t. \( \exists (l, v) \in S. v \models \psi_i \); \hspace{1cm} (11)
\( \psi'_a := \psi'_a \cup \Psi' \); \hspace{1cm} \( \psi'_n := \psi'_n \setminus \Psi' \) \hspace{1cm} (12)
endif
endif
endloop \hspace{1cm} (15)

Fig. 2. Iterative abstraction-refinement algorithm.
after a finite number of refinements, yielding a sound and complete decision procedure for checking whether or not a timed automaton satisfies a given TCTL formula.

**Theorem 3 (Termination, Soundness, and Completeness).** Let $M$ be a transition system with a corresponding finite basis $\Psi$, and $\varphi$ a TCTL formula. Then the algorithm in Figure 2 always terminates. Moreover, if it terminates with $\textbf{true}$, then $M \models \varphi$, and if the result is $\textbf{false}$, then $M \not\models \varphi$.

**Proof.** Let $n$ be the cardinality of the basis $\Psi$. Every execution of the loop (line (3)) adds at least one new predicate from the basis to the set $\Psi_n$ (line (12)). After at most $n$ iterations, according to Theorem 2, $\gamma[\alpha_c(\varphi)]^{M_{\Psi}} = \alpha_c(\varphi) \gamma[\varphi]^{M_{\Psi}}$. By Theorem 1, $\gamma(\alpha_c(\varphi)^{M_{\Psi}}) = \gamma(\alpha_c(\varphi)^{M_{\Psi}})$, and by Corollary 1, $M_{\Psi}$ satisfies the formula $\alpha_c(\varphi)$ if and only if $M$ satisfies $\varphi$. Thus, the algorithm terminates, since either $\varphi$ can be established or a concrete counterexample can be derived. \qed

**Example 1.** Consider the timed automaton from Figure 3, left side, for which we want to establish the property $\text{EG}(\leq 2 \ p)$. A given basis for this system and this property is $\Psi = \{x = 0, z = 0, x = 1, z = 1, x = 2, z = 2, x \geq 1, z \geq 1, x \leq 2, z \geq 2\}$. The transition system with the initial over-approximation using the abstraction predicates $\psi_0 \equiv (z \leq 2)$ and $\psi_1 \equiv (x \leq 1)$ is shown in the right side of Figure 3. Model checking the abstract formula $\varphi = \alpha_c(\text{EG}(\leq 2 \ p)) = \text{EG}(p \land \psi_0)$ on the transition system $M^{\alpha_c(\varphi)}_{(\psi_0,\psi_1)}$ returns $\textbf{false}$, since $s_0 = (l_0, x = z = 0) \not\in \gamma(\varphi)^{M^{\alpha_c(\varphi)}}$. The finite-state model-checking algorithm WMC [10,20] returns the symbolic counterexample $[X_0, X_1, X_2]$, where $X_0 = \{q_2, q_3\}, X_1 = \{q_1, q_2, q_3\}$, and $X_2 = \{q_0, q_1, q_2, q_3\}$. Recall the meaning of this counterexample list: the set $X_0$ consists of those states that do not satisfy the subformula $p \land \psi_0$, $X_1$ are the states in $X_0$ plus those states that can reach only states in $X_0$ in one step, and so forth. The concretization of this list of set of states is $[X^c_0, X^c_1, X^c_2]$ where $X^c_i \subseteq \gamma(X_i)$ for all $i = 0, 1, 2$.

$\gamma(X_0) = (l_2, z \leq 2 \land x \leq 1) \cup (l_3, z \leq 2 \land x \leq 1)$

$\gamma(X_1) = (l_2, z \leq 2 \land x \leq 1)$

$\gamma(X_2) = (l_3, z \leq 2 \land x \leq 1)$

\[\text{Example 3.}\] To simplify the notation we denote sets of concrete states such as \{(l_1, v) \mid l = l_0 \land v(x) < 1 \land v(z) \leq 2\} by $(l_0, x < 1 \land z \leq 2)$. 

---

**Fig. 3.** Timed automaton (left) and over-approximation with $\psi_0 \equiv (z \leq 2), \psi_1 \equiv (x \leq 1)$ (right) for Example 1.
The concretization of this counterexample yields

\[
\phi_1 \cup \text{atomic (boolean) proposition } l
\]

Example 2. Consider the timed automaton from the upper part in Figure 4. We want yields a spurious concrete counterexample, which initiates a refinement step.

We now illustrate a situation in which the concretization of the abstract counterexample yields a spurious concrete counterexample, which initiates a refinement step.

\[
\gamma(X_1) = \gamma(X_0) \cup (l_1, z \leq 2 \land x \leq 1)
\]
\[
\gamma(X_2) = \gamma(X_1) \cup (l_0, z \leq 2 \land x \leq 1)
\]

Now we have to check if the list \([X^c_0, X^c_1, X^c_2]\) is a counterexample on the concrete transition system, by checking the satisfiability of the conditions from Definition 2 (1). All four conditions are satisfied in our example, thus, the abstraction-refinement algorithm terminates with the answer \textbf{false}, meaning that the timed system from Figure 3 does not satisfy the property \(\text{EG}_{\leq 2} p\).

We now illustrate a situation in which the concretization of the abstract counterexample yields a spurious concrete counterexample, which initiates a refinement step.

*Example 2.* Consider the timed automaton from the upper part in Figure 4. We want to prove that location \(l_2\) is never reached, specified as \(\varphi = \neg\text{E}[\text{tt} \cup \text{at}_{l_2}]\), where the atomic (boolean) proposition \(\text{at}_{l_2}\) is true if the system is in location \(l_2\). Note that \(\varphi\) is actually a CTL formula, and need therefore not to be abstracted. \(\varphi\) can be rewritten as \(\text{AG}\neg\text{at}_{l_2}\). A given basis for this system is \(\mathcal{P} = \{x = 0, y = 0, x \leq 1, x \geq 1, y \leq 1, y \geq 1, x > y, x < y\}\). The transition system of the initial over-approximation with the single abstraction predicate \(\varphi_0 \equiv (x = 0)\) is shown in the lower left part of Figure 4. The transition system of the initial over-approximation with the single abstraction predicate \(\varphi_0 \equiv (x = 0)\) is shown in the lower left part of Figure 4.

Model checking \(\varphi = \text{AG}(\neg\text{at}_{l_2})\) on the transition system \(M_{\{x=0\}}\) returns \textbf{false}, since \(s_0 = (l_0, x = y = 0) \notin \gamma(\varphi)_{\{x=0\}}\). The list \([X_0, X_1, X_2, X_3]\), with \(X_0 = \{q_4\}, X_1 = \{q_3, q_4\}, X_2 = \{q_1, q_2, q_3, q_4\}, X_3 = \{q_0, q_1, q_2, q_3, q_4\}\) is returned as a counterexample. The concretization of this counterexample yields

\[
\gamma(X_0) = (l_2, x > 0 \land y \geq 0)
\]
\[
\gamma(X_1) = (l_1, x > 0 \land y \geq 0) \cup (l_2, x > 0 \land y \geq 0)
\]
\[
\gamma(X_2) = (l_0, x > 0 \land y \geq 0) \cup (l_1, x \geq 0 \land y \geq 0) \cup (l_2, x > 0 \land y \geq 0)
\]
\[
\gamma(X_3) = (l_0, x \geq 0 \land y \geq 0) \cup (l_1, x \geq 0 \land y \geq 0) \cup (l_2, x > 0 \land y \geq 0)
\]
Now, we have to check if there is a corresponding symbolic counterexample on the concrete system, that is, there exists \( [X_0^c, X_1^c, X_2^c] \), with \( X_i^c \subseteq \gamma(X_i) \), for all \( i = 0, \ldots, 3 \). This is the case if the following formula is valid.

\[
\phi = \exists X_0^c \subseteq \gamma(X_0), \ldots, X_3^c \subseteq \gamma(X_3), \exists C' \subseteq S.
\]

\[
(M \not\models C' \Rightarrow \neg \text{at}_{l_2}) \land (X_0^c = C') \land \lambda_{i=0}^2 (X_{i+1}^c \Rightarrow (X_i^c \lor \text{pre}(N)(X_i^c))
\]

Here, \( \phi \) is not satisfiable, since on the concrete transition system \( X_2^c \not\subseteq (X_1^c \lor \text{pre}(N)(X_1^c)) \) does not hold. \( X_1^c \lor \text{pre}(N)(X_1^c) = (l_2, x > 0 \land y \geq 0) \cup (l_1, x > y \geq 0) \) does not contain a state with location \( l_0 \), but according to Definition 11 and the fact that \( X_2^c \subseteq \gamma(X_2) \), \( X_2^c \) must contain a state with a \( l_0 \) location, and therefore \( X_2^c \not\subseteq (X_1^c \lor \text{pre}(N)(X_1^c)). \)

Now, \( k = 1 \) in our abstraction refinement algorithm, and \( S = \{(l_1, 0) \mid v(x) > v(y)\} \), and the new abstraction predicate is chosen to be \( \psi_1 \equiv x > y \). Figure 4 (lower right part) shows the reachable fragment of the resulting approximation of \( M \) with \( \Psi = \{\psi_0, \psi_1\} \). Model checking the formula \( \varphi = \varphi_{\text{AG}}(\neg \text{at}_{l_2}) \) on \( M_{\{\psi_0, \psi_1\}} \) succeeds, since \( s_0 = (l_0, \psi_0 \land \neg \psi_1) \in \gamma([\varphi,M_{\{\psi_0, \psi_1\}}]). \)

6 Conclusion

We have defined symbolic counterexamples for the full TCTL logic, and used them for developing a verification algorithm for timed automata based on predicate abstraction, untimed model checking, and decision procedures for the Boolean combination of linear arithmetic constraints. The main advantage of this approach is that finite state abstractions are computed lazily and incrementally. Abstraction refinement terminates quickly, as a multitude of spurious counterexamples is eliminated in every refinement step through the use of symbolic counterexamples for TCTL. Using symbolic counterexamples makes it possible to apply the abstraction refinement paradigm to the full TCTL logic.

Dual to the notion of symbolic counterexamples, we can also define symbolic witnesses for the full TCTL, as extensions of symbolic witnesses for CTL [20]. These witnesses and counterexamples can be seen as proofs for the judgment that the timed automaton does or does not satisfy the given TCTL formula, and can be independently verified using a satisfiability checker that can decide the theory of linear arithmetic with reals. Moreover, explicit linear or tree-like witnesses and counterexamples can be extracted from these symbolic evidence, following the approach in [20] for the untimed case.

The method of lazy approximation is also applicable for other real-time logics. Moreover, this technique can readily be extended to also apply to richer models than timed automata, such as parameterized timed automata, timed automata with other infinite data types, or even to hybrid systems. The price to pay is that such extensions are necessarily incomplete.

Work in progress investigates the combination of lazy approximation with the approach to controller synthesis for finite-state systems presented in [20], for synthesizing real-time controllers.

A TCTL Syntax and Semantics

Definition 12 (TCTL Syntax). Let \( AP \) be a set of atomic propositions, and \( p \in AP \). The formulas of TCTL are inductively defined as follows:

\[
φ := p \mid ¬φ \mid φ_1 \land φ_2 \mid E[φ_1 U_c φ_2] \mid A[φ_1 U_c φ_2]
\]

Definition 13 (s-Path). For a set \( S \) of states and \( s \in S \), an \( s \)-path through \( S \) is a map \( ρ \) from \( \mathbb{R}_{≥0} \) to \( S \), satisfying \( ρ(0) = s \).

Definition 14 (TCTL-Structure). A structure for a TCTL formula is a tuple \( M = \langle S, S_0, µ, f \rangle \), where

- \( S \) is a set of states.
- \( S_0 \in S \) is an initial state.
- \( µ : S → \mathcal{P}(AP) \) is a labeling function, which assigns to each state a set of atomic propositions true in that state.
- \( f \) is a map, which assigns to every \( s \in S \) a set of \( s \)-paths through \( S \), and is closed under suffix and fusion.

Definition 15 (Semantics of TCTL). Given a TCTL-structure \( M = \langle S, S_0, µ, f \rangle \), over a set \( S = L \times V_C \), of timed configurations, and a TCTL-formula \( φ \), the set of states \( [ [ φ ] ]^M \), which validates the formula \( φ \) is defined inductively over the structure of \( φ \).

\[
[[p]]^M := \{ s \in S \mid p \in µ(s) \}
\]
\[
[[¬φ]]^M := S \setminus [[φ]]
\]
\[
[[φ_1 \land φ_2]]^M := [[φ_1]]^M \land [[φ_2]]^M
\]
\[
[[E[φ_1 U_c φ_2]]^M := \{ s \in S \mid \text{for some } ρ \in f(s), \text{ for some } t \sim c, ρ(t) \in [[φ_2]]^M \text{ and } ρ(t') \in [[φ_1]]^M, \text{ for all } 0 ≤ t' < t}]
\]
\[
[[A[φ_1 U_c φ_2]]^M := \{ s \in S \mid \text{for all } ρ \in f(s), \text{ for some } t \sim c, ρ(t) \in [[φ_2]]^M \text{ and } ρ(t') \in [[φ_1]]^M, \text{ for all } 0 ≤ t' < t}]
\]

Definition 16 (Other Temporal Operators). The following temporal operators can be defined as usual.

\[
EF_c φ := E[tt U_c φ]
\]
\[
AF_c φ := A[tt U_c φ]
\]
\[
EG_c φ := ¬AF_c ¬φ
\]
\[
AG_c φ := ¬EF_c ¬φ
\]
\[
E[φ_1 R_c φ_2] := E[¬φ_1 U_c ¬φ_2]
\]
\[
A[φ_1 R_c φ_2] := A[¬φ_1 U_c ¬φ_2]
\]

Details on suffix and fusion closure can be found in [1].
B  Symbolic Counterexamples for TCTL

Definition 17 (TCTL Symbolic Counterexamples). Let $M = (S, S_0, P, N)$ be a transition system, where $S = L \times V_C$, $S_0 \subseteq S$, and $N$ is the transition relation. For a TCTL formula $\varphi$, and a set of states $C \subseteq S_0$, a symbolic counterexample $c$ justifying $M, C \not\models \varphi$ has the form $X^m$, where $X$ is a sequence of states of length $m + 1$, which is defined inductively over the structure of $\varphi$. Note that $(c_1, \ldots, c_k) \models M, C_1 \cup \ldots \cup C_k \not\models \varphi$ iff $c_i \models M, C_i \not\models \varphi$ for $1 \leq i \leq k$.

1. A counterexample $c \models M, C \not\models \text{EG}_c \varphi$ is a list $c = X^m$, such that $\exists C' \subseteq S$ with (a) $M, C' \not\models \varphi \land \zeta$, (b) $X_0 \subseteq C'$, (c) $X_{i+1} \subseteq X_i \cup \pre(N)(X_i)$, for $i < m$, (d) $C = X_m$.
2. A counterexample $c \models M, C \not\models \text{AG}_c \varphi$ is a list $c = X^m$, such that $\exists C' \subseteq S$ with (a) $M, C' \not\models \varphi \land \zeta$, (b) $X_0 \subseteq C'$, (c) $X_{i+1} \subseteq X_i \cup \pre(N)(X_i)$, for $i < m$, (d) $C = X_m$.
3. A counterexample $c \models M, C \not\models \text{EF}_c \varphi$ is a list $c = X^m$, such that $\exists C' \subseteq S$ with (a) $M, C' \not\models \varphi \land \zeta$, (b) $X_0 \subseteq C'$, (c) $X_{i+1} \subseteq X_i$, for $i < m$, (d) $C = X_m \subseteq \pre(N)(X_m)$.
4. A counterexample $c \models M, C \not\models \text{AF}_c \varphi$ is a list $c = X^m$, such that $\exists C' \subseteq S$ with (a) $M, C' \not\models \varphi \land \zeta$, (b) $X_0 \subseteq C'$, (c) $X_{i+1} \subseteq X_i$, for $i < m$, (d) $C = X_m \subseteq \pre(N)(X_m)$.
5. A counterexample $c \models M, C \not\models \text{E}[\varphi_1 \cup_c \varphi_2]$ is a list $c = X^m$, such that $\exists C', C'' \subseteq S$ with (a) $M, C'' \not\models \varphi_2 \land \zeta$, and $M, C' \not\models \varphi_1 \lor \varphi_2 \land \zeta$, (b) $C' \subseteq X_0 \subseteq C''$, (c) $X_{i+1} \subseteq (\pre(N)(X_i) \cap X_i) \cup C'$, (d) $C = X_m \subseteq \pre(N)(X_m)$.
6. A counterexample $c \models M, C \not\models \text{A}[\varphi_1 \cup_c \varphi_2]$ is a list $c = X^m$, such that $\exists C', C'' \subseteq S$ with (a) $M, C'' \not\models \varphi_2 \land \zeta$, and $M, C' \not\models \varphi_1 \lor \varphi_2 \land \zeta$, (b) $C' \subseteq X_0 \subseteq C''$, (c) $X_{i+1} \subseteq (\pre(N)(X_i) \cap X_i) \cup C'$, (d) $C = X_m \subseteq \pre(N)(X_m)$.
7. A counterexample $c \models M, C \not\models \text{E}[\varphi_1 \land_c \varphi_2]$ is a list $c = X^m$, such that $\exists C', C'' \subseteq S$ with (a) $M, C'' \not\models \varphi_2 \land \zeta$, and $M, C' \not\models \varphi_1 \lor \varphi_2 \land \zeta$, (b) $C' \subseteq X_0 \subseteq C''$, (c) $X_{i+1} \subseteq (\pre(N)(X_i) \cap C') \cup X_i$, (d) $C = X_m$.
8. A counterexample $c \models M, C \not\models \text{A}[\varphi_1 \land_c \varphi_2]$ is a list $c = X^m$, such that $\exists C', C'' \subseteq S$ with (a) $M, C'' \not\models \varphi_2 \land \zeta$, and $M, C' \not\models \varphi_1 \lor \varphi_2 \land \zeta$, (b) $C' \subseteq X_0 \subseteq C''$, (c) $X_{i+1} \subseteq (\pre(N)(X_i) \cap C') \cup X_i$, (d) $C = X_m$.
9. A counterexample $c \models M, C \not\models \varphi_1 \lor \varphi_2$ is a list $c = X^m$, such that $\exists C', C'' \subseteq S$ with (a) $M, C' \not\models \varphi_1$, and $M, C'' \not\models \varphi_2$, (b) $C = X_0 = C' \cap C''$.
10. A counterexample $c \models M, C \not\models \varphi_1 \land \varphi_2$ is a list $c = X^m$, such that $\exists C', C'' \subseteq S$ with (a) $M, C' \not\models \varphi_1$, and $M, C'' \not\models \varphi_2$, (b) $C = X_0 = C' \cup C''$.
