Implicit characterizations of FPTIME and NC revisited

Karl-Heinz Niggl∗ Henning Wunderlich†

July 8, 2008

Abstract

Various simplified or improved, and partly corrected well-known implicit characterizations of the complexity classes FPTIME and NC are presented. Primarily, the interest is in simplifying the required simulations of various recursion schemes in the corresponding (implicit) framework, and in developing those simulations in a more uniform way, based on a step-by-step comparison technique, thus consolidating groundwork in implicit computational complexity.

1 Introduction

In implicit computational complexity, much attention has been payed to the complexity classes FPTIME and NC, e.g. see [2, 4, 6, 7, 9, 10, 15, 18, 19, 24, 26]. This paper presents simplified or improved, and partly corrected well-known implicit characterizations of the complexity classes FPTIME and NC.

The core of the present research is to simplify the required simulations of various (bounded) recursion schemes in the corresponding (implicit) framework, and moreover, to develop those simulations in a more uniform way, based on a step-by-step comparison technique. Furthermore, we establish a new ground type function algebraic characterization of NC, which might be of help to resolve the open problem [2] of characterizing NC through higher types.

The starting point is a simplified proof that the functions of Cobham’s class, Cob [12], characterizing FPTIME is contained in the function algebra BC of Bellantoni and Cook [4]. That every function f of Cobham’s class can be simulated in BC rests on three findings:

(S1) For every f in Cob one can construct a function f′(w;⃗x) in BC, called simulation of f, and a polynomial pf, called witness for f, such that

\[ f(⃗x) = f′(w;⃗x) \text{ whenever } |w| \geq pf(|⃗x|). \]

(S2) For every polynomial p(⃗x) one can construct a function Wp(⃗x; ) in BC, called length-bound on p, such that |Wp(⃗x; )| \geq p(|⃗x|).

†Universität Ulm, Fakultät für Ingenieurwissenschaften und Informatik, Institut für Theoretische Informatik, Obere Eißlingerstrasse 69, D-89069 Ulm, e-mail: Henning.Wunderlich@uni-ulm.de
Every function $g(\vec{x}, \vec{y}, \vec{z})$ in BC can be written as $\text{SN}(g)(\vec{x}, \vec{y}; \vec{z})$, called safe-to-normal property.

Thus, by use of (S1), (S2), (S3), and safe composition, the proof that every $f$ in Cob can be simulated in BC is then concluded as follows:

$$f(\vec{x}) = \text{SN}(f')(W_p(\vec{x}'), \vec{x};)$$

In each simulation, we will concentrate on the crucial statement corresponding to (S1). As for (S1) above, all cases are obvious, except for the case where $f$ is defined by bounded recursion on notation, and here a difficult simulation and proof was given in [4]. The difficulty mainly arises because of an unnatural choice of a case function defined as

$$\text{case}(;x, \text{even}, \text{odd}) := \begin{cases} 
\text{even} & \text{if } x \text{ is even} \\
\text{odd} & \text{if } x \text{ is odd.}
\end{cases}$$

When replacing function case by the function bcase (for binary case), that is,

$$\text{bcase}(;x, \text{zero}, \text{even}, \text{odd}) := \begin{cases} 
\text{zero} & \text{if } x = 0 \\
\text{even} & \text{if } x > 0 \text{ and } x \text{ is even} \\
\text{odd} & \text{if } x > 0 \text{ and } x \text{ is odd}
\end{cases}$$

then a simulation $f'$ can be constructed the correctness of which is immediate from its definition. So let BC' be BC where case is replaced with bcase.

Note that both case and bcase (as well as the binary predecessor function p) could be defined by recursion on notation and composition, using projections and the constructor functions 0, s0, s1. But in both algebras BC and BC', this is only possible at the cost of introducing normal input positions, and that is why they come as initial functions with safe input positions only. But then we have a choice between case and bcase. We clearly opt for bcase because it is the natural choice. In fact, bcase naturally springs from a “flat” recursion on notation, since that scheme distinguishes the cases zero, nonzero and even and nonzero and odd.

Furthermore, note that while bcase( ; $x, y, z_0, z_1$) is provably indencifiable in BC, the function case( ; $x, z_0, z_1$) is obviously in BC', since case( ; $x, z_0, z_1$) = bcase( ; $x, z_0, z_0, z_1$).

To our knowledge, the “simulation method” (S1) appears for the first time in the groundwork of Bellantoni and Cook [4]. Since then, it has been applied directly or in adapted form to many characterizations of complexity classes, e.g. the Kálmárn-elementary functions and Pspace are treated in [25], in [20], [5] the method is extended to all levels of the Grzegorczyk hierarchy, and in [15] that method is adapted so as to compute all functions at Grzegorczyk level $n+2$ by loop programs of $\mu$-measure $n$.

Roughly speaking, the simulation method consists in separating the “structure” in a recursion from the “growth rate” given with it. Technically, one introduces a single normal parameter, $w$, to which all given recursion parameters refer to in a “safe” way. It is hard to say what those simulations compute for wrong values of $w$, however, once $w$ is sufficiently large, and that is where the witness comes into play, all given recursions unfold in the expected way.

1As a technical consequence, in BC' we don't have to bother with defining the functions “PARITY", "T", "V" or "H", unlike in [4].
Our way of performing the simulation method for various forms of recursion does not change that at all. However, unlike many instances of that method in the literature, we always start off with a clear semantics based on a step-by-step comparison technique such that when implementing the simulation in the given framework, the correctness of the implementation is immediate from the specified semantics. As pointed out above, the right choice of initial functions, such as $\text{base}$, will sometimes prove decisive.

Rounding off, the main goal is to propose a step-by-step comparison technique, exemplified at various forms of recursion, so as to perform the simulation method in a way that is easy to grasp and does away with hard going proofs. Thereby, groundwork in implicit computational complexity is revised and consolidated.

The paper is organized as follows. In Section 2, all basic notions involved in the design of Cobham’s and Bellantoni/Cook’s function algebra, $\text{Cob}$ and $\text{BC}$, are introduced and examined. Section 3 presents a simplified proof of $\text{BC}' = \text{Cob}$, thereby demonstrating the step-by-step comparison technique. Recalling Clote’s function algebra, $\text{CLO}$, in Section 4 and 5, two variants, $\text{CLO}'$ and $\text{CLO}''$, are considered, and a proof of $\text{CLO}' = \text{CLO} = \text{CLO}''$ is presented, using the same technique. In Section 6 several ramified function algebras are introduced, and, using both the step-by-step comparison technique and the above identities, it is proved that all of them characterize the class $\text{NC}$.

2 Preliminaries and some existing function algebras

We assume only basic knowledge about the function algebras and complexity classes studied here. In this section, we introduce to and summarize some basic concepts, and make some stipulations concerning notations used throughout this article.

Albeit describing operations on binary representations, all of the functions under consideration are number-theoretic, that is, functions of the form $f : \mathbb{N}^n \to \mathbb{N}$. For unary functions $f$ and numbers $k$, $f^k$ denotes the $k$th iterate of $f$, inductively defined by $f^0(x) = x$ and $f^{k+1}(x) = f(f^k(x))$.

Binary representations of natural numbers $x$, denoted by $\text{bin}(x)$, can be simulated by 0 (viewed as $0$-ary function) and the binary successors $S_0, S_1$ which correspond to the operations of extending binary representations by a new lowest order bit.

$$S_0(x) = 2 \cdot x \quad (\text{operation } \text{bin}(x) \mapsto \text{bin}(x)0 \text{ for } x \neq 0)$$
$$S_1(x) = 2 \cdot x + 1 \quad (\text{operation } \text{bin}(x) \mapsto \text{bin}(x)1)$$

This “data structure” gives rise to a canonical recursion scheme: A function $f$ is defined by recursion on notation from functions $g, h_0, h_1$, denoted by $f = \text{RN}(g, h_0, h_1)$, if for all $y, \bar{x}$,

$$f(0, \bar{x}) = g(\bar{x})$$
$$f(S_i(y), \bar{x}) = h_i(y, \bar{x}, f(y, \bar{x})) \quad \text{for } S_i(y) \neq 0.$$ 

Observe that $\text{bin}(g) = b_{l-1} \ldots b_0 \neq \epsilon$ implies $y = S_{h_0}(S_{h_1}(\ldots S_{h_{l-1}}(0) \ldots))$. Thus, for recursion on notation, the recourse is from $b_{l-1} \ldots b_0$ to $b_{l-1} \ldots b_1$ to $\ldots$ to
Theorem 2.1. Computable functions are precisely the functions denable in $\text{Cob}$ (in the binary length of the input). Cobham showed that the polynomial-time is, the functions computable (in binary) on a Turing machine in polynomial time $\leq 1$ principle (P-BC) by ensuring the following:

- Where were the first to give a purely functional characterization of $\text{FPTIME}$ (cf. [21], [23]).
- Must not control other recursions in Cobham's class. In fact, this explicit reference can be made implicit.
- Is bounded by some function already constructed.
- Easily verifies that for every function $f$ in Cob the polynomial length bound on $f$, that is, a polynomial $b_f$ satisfying $|f(\vec{x})| \leq b_f(|\vec{x}|)$.
- While the latter is a necessary condition for all functions in $\text{FPTIME}$, that is, the functions computable (in binary) on a Turing machine in polynomial time (in the binary length of the input), Cobham showed that the polynomial-time computable functions are precisely the functions definable in Cob.

**Theorem 2.1 ([12]).** \text{Cob} = \text{FPTIME}

From a programming point of view, function algebras like Cob are not practically appealing because they cannot be used as a construction kit: Whenever a recursion is performed, one is prompted with a proof that the computed function is bounded by some function already constructed.

Building on work of Simmons [27] and Leivant [16, 17], Bellantoni and Cook [4] were the first to give a purely functional characterization of $\text{FPTIME}$ that does away with the "explicit" reference to the growth rate of functions defined by (BRN) in Cobham's class. In fact, this "explicit" reference can be made "implicit" by ensuring the following principle (P-BC): Computed values in recursions must not control other recursions (cf. [21], [23]).

That principle led to the well-known function algebra BC [4] which actually can be used as a construction kit, since all restrictions are of purely syntactical nature. In BC, each function is written in the form $f(\vec{x}; \vec{y})$, thus bookkeeping the normal input positions, $\vec{x}$, which may control a recursion, and those (safe), $\vec{y}$, which do not. This simple bookkeeping allows us to implement (P-BC): A function $f(y, \vec{x}; \vec{a})$ is defined by safe recursion from $g(\vec{x}; \vec{a}), h_0(u, \vec{x}; \vec{a}, v)$, and $h_1(u, \vec{x}; \vec{a}, v)$, denoted by $f = \text{sm}(g, h_0, h_1)$, if for all $y, \vec{x}, \vec{a}$,

\[
\begin{align*}
    f(0, \vec{x}; \vec{a}) &= g(\vec{x}; \vec{a}) \\
    f(S_i(y), \vec{x}; \vec{a}) &= h_i(y, \vec{x}; \vec{a}, f(y, \vec{x}; \vec{a})) \quad \text{for } S_i(y) \neq 0.
\end{align*}
\]

Enforcing the above principle when composing functions of given ones, a function $f(\vec{x}; \vec{a})$ is defined by safe composition from functions $g(\vec{a}; v), h(\vec{x}; \vec{a})$, and
\[ j(x; a), \text{ denoted by } f = \text{scomp}(g, \tilde{h}, j), \text{ if for all } x, a, \]
\[ f(x; a) = g(h(x; j(x; a))). \]

Of course, now all initial functions must be written in a ramified form, too. These are the functions 0, \( s_0(\cdot ; y) \), \( s_1(\cdot ; y) \), \( \pi^{n,m}_i(x; y) \), \( p(\cdot ; y) \), and \( \text{case}(\cdot ; x, y, z) \), where the latter is defined in Section 1. The function \( p(\cdot ; y) \) is the ramified form of the binary predecessor \( P \) satisfying \( P(x) = \lfloor \frac{x}{2} \rfloor \), and thus corresponds to the operation of chopping off the lowest order bit, if any.

Note that the projections \( \pi^{n,m}_i(x_1, \ldots, x_n; x_{n+1}, \ldots, x_{n+m}) = x_i \), for \( 1 \leq i \leq n+m \), are the only initial functions with normal input positions. It is their presence that is in charge of the safe-to-normal property, (S3), stated in Section 1. To see this, let \( f(x; \tilde{y}, \tilde{z}) \) be in \( \text{BC} \), say \( x = x_1, \ldots, x_i; \tilde{y} = x_{i+1}, \ldots, x_n \) with \( n := l+m \), and \( \tilde{x} = x_{n+1}, \ldots, x_s \) with \( s := n+r \). Then by scomp we obtain
\[ \text{SN}(f)(\tilde{x}, \tilde{y}, \tilde{z}) = f(\pi^{0,0}_0(\tilde{x}, \tilde{y})), \ldots, \pi^{0,0}_i(\tilde{x}, \tilde{y}); \pi^{n,r}_1(\tilde{x}, \tilde{y}, \tilde{z}), \ldots, \pi^{n,r}_s(\tilde{x}, \tilde{y}, \tilde{z})). \]

In particular, this shows that normal variables may occur in any safe position in the right-hand side of any defining equation according to scomp.

Furthermore, note that both \( h(\tilde{x}; \cdot) \) and \( j(x; a) \) in scheme scomp may be empty function lists. Thus, all \( n \)-ary constant functions \( C^n_a(\tilde{x}; \tilde{y}) = a \) can be defined in \( \text{BC} \): \( C^n_0(\tilde{x}; \tilde{y}) = 0 \), and inductively for 2 \( a + i \geq 1 \), \( C^n_{2a+1}(\tilde{x}; \tilde{y}) = s_i(\cdot ; C^n_a(\tilde{x}; \tilde{y})) \). As a consequence, every constant \( a \) may occur in the right-hand side of any defining equation according to scomp or srm.

Altogether, the function algebra \( \text{BC} \) can be stated as
\[ \text{BC} := [0, s_0, s_1, \pi, p, \text{case}; \text{scomp, srm}] \]
where \( \pi \) denotes the set of all ramified projections.

This function algebra is a prominent example of a ramified algebra, and as done here, for the remainder we will adopt the convention that ramified versions of functions written in capital letters, like \( S, P \) or BIT, are written in small letters, like \( s, p \) or \( \text{bit} \), and if not explicitly stated otherwise, we tacitly assume that they have safe input positions only.

The benefit of ramification can be seen by the fact, verified by a straightforward induction on the structure of functions in \( \text{BC} \), that for every function \( f(x; \tilde{y}) \) there exists a poly-max length bound, that is, a polynomial \( q_f \) satisfying
\[ |f(x; \tilde{y})| \leq q_f(|\tilde{x}|) + \max(|\tilde{y}|). \]

Using this poly-max length bounding, every recursion in \( \text{BC} \) can be written as bounded recursion in Cobham’s class, implying \( \text{BC} \subseteq \text{Cob} \). The converse holds by simulating the functions of \( \text{Cob} \) in \( \text{BC} \), and that brings us back to the main topic of the present research.

**Theorem 2.2** ([4]). \( \text{BC} = \text{FPTIME} \)

Rounding off this section, we prove property (S2) stated in Section 1. First note that the shift-left function \( \text{shl}(x; y) = 2^{|x|} \cdot y \) is defined by srm as follows:
\[ \text{shl}(0; y) = \pi^{0,1}_1(\cdot ; y), \]
\[ \text{shl}(S_i(x); y) = s_0(\cdot ; \text{shl}(x; y)) \quad \text{for } S_i(x) \neq 0 \]

5
Following the simulation method \(Cob\) only consider the crucial case \((S2)\).

As \(2^{(|x|+1)+|y|} = 2^{|y|} \cdot 2^{|x|+|y|}\), the smash function \(\#(x,y; ) = 2^{|x|+|y|}\) is defined by

\[
\#(0, y; ) = 1
\]

\[
\#(S_i(x), y; ) = \text{shl}(\pi_2^{n, 0}(x, y; ); \#(x, y; )) \text{ for } S_i(x) \neq 0.
\]

Now, to prove \((S2)\), we proceed by induction on the structure of polynomials \(p(\tilde{x})\) in \(N[\tilde{x}]\). If \(p(x_1, \ldots, x_n) = x_i\) or \(c\), then \(W_y(\tilde{x}; ) := \text{shl}(\pi_2^{n, 0}(\tilde{x}; ); 1)\) and \(W_c(\tilde{x}; ) := C_{n, 2}(\tilde{x}; )\), respectively, will do. Otherwise \(p(\tilde{x}) = p_1(\tilde{x}) \circ p_2(\tilde{x})\) with \(\circ \in \{+,-\}\), and using \(x + y, x - y \leq (x + 1) \cdot (y + 1)\) and \(2^{|x|} = x + 1\), we inductively define the required function \(W_y(\tilde{x}; )\) by safe composition as follows:

\[
W_y(\tilde{x}; ) := \#(s_1(; W_{p_1}(\tilde{x}; )), s_1(; W_{p_2}(\tilde{x}; ));
\]

3 The variant \(BC'\) and the step-by-step comparison technique

In this section, we will give a simplified proof of \(BC' = Cob\), for the following variant \(BC'\) of Bellantoni and Cook's function algebra (cf. Section 1 for base).

\[
BC' := [0, s_0, s_1, \pi, p, \text{case; scomp; srn}]
\]

**Theorem 3.1.** \(BC' = \text{FPTIME.}\)

**Proof.** \([\text{Cob} \subseteq \text{BC'}]\) Following the simulation method \((S1)\) stated above, we only consider the crucial case \(f = \text{BRN}(g, h_0, h_1, B)\), assuming inductively simulations \(g', h'_0, h'_1 \in BC'\) and witnesses \(p_g, p_{h_0}, p_{h_1}\). As usual, the witness for \(f\) is defined by \(p_f(y, \tilde{x}) := (p_{h_0} + p_{h_1})(y, \tilde{x}, b_f(y, \tilde{x}) + p_g(\tilde{x}) + 2|y| + 1)\) for some polynomial length bound \(b_f\) on \(f\). Thus, by monotonicity of polynomials, we have that \(\forall y \in \mathbb{N}, \forall p_f(y, \tilde{x}) \in [P^1(y, \tilde{x}), f(P^1(y, \tilde{x}))]\) whenever \(|w| \geq p_f(y, \tilde{x})\). Now, for any \(y, i \in \mathbb{N}, \text{let}\)

\[
y\{i\} := P^i(y)
\]

be the \(y\)-section up to \(i\). That is, for given \(y = (b_{i-1} \cdots b_0)_2\) with \(\text{bin}(y) = b_{i-1} \cdots b_0\), we have \(y\{i\} = (b_{i-1} \cdots b_i)_2\), and \(y\{i\} \text{ mod } 2 = b_i\) for \(i < |y|\). Thus, by unfolding the recursion we obtain the following steps:

\[
f(y, \tilde{a}) = h_{y\{0\} \text{ mod } 2}(y\{1\}, \tilde{a}), \quad \text{step 1}
\]

\[
h_{y\{i-1\} \text{ mod } 2}(y\{i\}, \tilde{a}), \quad \text{step } i
\]

\[
h_{y\{|y|-1\} \text{ mod } 2}(y\{|y|\}, \tilde{a}, g(\tilde{a}) \cdots), \quad \text{step } |y|
\]

\[
h_{y\{|y|+1\} \text{ mod } 2}(y\{|y|\}, \tilde{a}, g(\tilde{a}) \cdots) \cdots, \quad \text{step } |y| + 1
\]

We will define a simulation \(f' \in BC'\) by

\[
f'(w; y, \tilde{a}) := f(w, w; y, \tilde{a})
\]
where \( \hat{f} := \text{srn}(0,\bar{h},\bar{h})\) is defined by safe recursion from the zero function and some \( \bar{h} \in \text{BC}'\). Again, unfolding the recursion yields the following \( \hat{f} \)-steps:

\[
\begin{align*}
\hat{f}(w, w; y, \bar{a}) &= \hat{h}(P^1(w), w; y, \bar{a},) & \text{step 1} \\
\vdots \\
\hat{h}(P^i(w), w; y, \bar{a},) &= \hat{h}(P^{|y|+1}(w), w; y, \bar{a},) & \text{step } |y| \\
\hat{h}(P^{|y|+1}(w), w; y, \bar{a},) &= \hat{h}(P^{|y|+1}(w), w; y, \bar{a},) & \text{step } |y| + 1 \\
\cdots (0) \cdots) & \text{step } > |y| + 1
\end{align*}
\]

Thus, for \( f(y, \bar{a}) = \hat{f}(w, w; y, \bar{a})\) whenever \(|w| \geq p_f(|y, \bar{a}|)\), using the I.H. for \( g, h_0, h_1 \) recall (\( \ast \)) – a stepwise comparison yields the following requirements:

\[
\begin{align*}
\hat{h}(P^i(w), w; y, \bar{a}, v_i) &= h'(y^{(i-1)} \bmod 2)(w; y\{i\}, \bar{a}, v_i) & \text{in steps } 1 \leq i \leq |y| \\
\hat{h}(P^{|y|+1}(w), w; y, \bar{a}, v_{|y|+1}) &= g'(w; \bar{a}) & \text{in step } |y| + 1
\end{align*}
\]

where \( v_i := f(P^i(y), \bar{a}) \) for \( i = 1, \ldots, |y| + 1 \). Now, defining \( \ominus (w, v) := P^{|w|}(v) \) by (srn), and hence \( |\ominus (w, v)| = |v| - |w| \), by safe composition we obtain the following \( y \)-section implementation in \( \text{BC}' \).

\[
Y(w, y) := \ominus (\text{SN}(\ominus) (\hat{w}, w); y) = P^{|w| - |\hat{w}|}(y) = y(\{w\} - |\hat{w}|)
\]

In fact, for sufficiently large \( w \), that is, for \(|w| \geq p_f(|y, \bar{a}|)\), one has that

\[
Y(P^i(w), w; y) = \begin{cases} y\{i\} & \text{if } i \leq |y| \\ 0 & \text{if } |y| \leq i \leq |w| \end{cases}
\]

Thus, using function \( \text{bcase} \) above, function \( \bar{h} \) can be defined in \( \text{BC}' \) as follows:

\[
\bar{h}(\hat{w}, w; y, \bar{a}, v) := \text{bcase} ( : Y(S_1(\hat{w}, w; y), \bar{a}, v),
\end{align*}
\]

\[
\begin{align*}
\hat{h}(P^i(w), w; y, \bar{a}, v_i) &= \text{bcase} ( : y\{i-1\}, g'(w; \bar{a}), T_0, T_1) \\
&= h_{y\{i-1\} \bmod 2}(w; y\{i\}, \bar{a}, v_i) & \text{as } y\{i-1\} > 0,
\end{align*}
\]

and \( \bar{h}(P^{|y|+1}(w), w; y, \bar{a}, v_{|y|+1}) = \text{bcase} ( : 0, g'(w; \bar{a}), \cdots, \cdots = g'(w; \bar{a}) \).

The converse \( \text{BC}' \subset \text{Cob} \) follows by a straightforward induction on the structure of \( f(x; \bar{a}) \) in \( \text{BC}' \), using polymax length bounding to turn any safe recursion on notation into a bounded recursion in \( \text{Cob} \) (cf. [4] or [20], [22]). \( \square \)

### 4 Clote’s function algebra CLO and its variant CLO'

In this section, we first recall Clote’s [10, 11] function algebra, CLO, that characterizes the class \( \text{NC} \) of functions computable by uniform circuit families of
polynomial size and poly-logarithmic depth. Then we consider a variant \( \text{CLO}' \) due to Bellanoni [3], and prove that these classes coincide.

To define \( \text{CLO} \), we need two more schemes and the function \( \text{BIT} \) satisfying \( \text{BIT}(m,i) = b_i \) if \( \bin(m) = b_{i-1} \ldots b_0 \) and \( i < l \), and \( \text{BIT}(m,i) = 0 \) otherwise.

A function \( f \) is defined by weak bounded recursion on notation from functions \( g, h, B \), denoted by \( : = \text{WBRN} \), if it satisfies \( f(y, \bar{a}) = F(|y|, \bar{a}) \), for \( F = \text{BRN} \).

Furthermore, a function \( f \) is defined by concatenation recursion on notation from functions \( g, h, B \), denoted by \( : = \text{CRN} \), if for all \( y, \bar{a} \),

\[
\begin{align*}
&f(0, \bar{a}) = g(\bar{a}) \\
&f(y, \bar{a}) = h(y, \bar{a}, f(\text{H}(y), \bar{a})) \quad \text{for } y \neq 0 \\
&f(y, \bar{a}) \leq B(y, \bar{a})
\end{align*}
\]

where the half function \( \text{H} \) is defined by \( \text{H}(m) := \lfloor m/2^{\lceil \log_2(m) \rceil} \rfloor \).

The behavior of function \( \text{H} \) can be easily expressed on binary representations:

\[
\begin{align*}
\text{H}(b_{2n-1} \ldots b_0) &= (b_{2n-1} \ldots b_n)_2 \quad \text{even length} \\
\text{H}(b_{2n} \ldots b_0) &= (b_{2n} \ldots b_{n+1})_2 \quad \text{odd length}
\end{align*}
\]

In fact, defining the class \( \text{CLO}' \) by

\[
\text{CLO}' := [0, S_0, S_1, \Pi, | \cdot |, \text{BIT, #}; \text{COMP, CRN, WBRN}']
\]

one obtains the following result.

**Theorem 4.3.** \( \text{CLO} = \text{CLO}' \)

As the proof sketch in [3, footnote on p. 73] of either inclusion is wrong\(^2\), we give a proof of the above theorem – the first one according to our knowledge –, using the above step-by-step comparison technique.

---

\(^2\)Any \( f = \text{WBRN}(g, h, B) \) is claimed to be identical to \( f' = \text{WBRN}(g', B) \), where \( h'(x, \bar{v}, z) := h_{[x] \mod 2^l}(-1, \bar{v}, z) \). But, for example, \( f(5, \bar{v}) = F(S_1(0), \bar{v}) = h_1(\bar{v}, h(0, \bar{v}, g(\bar{v}))) \), while \( f'(5, \bar{v}) = h'(5, \bar{v}, h'(1, \bar{v}, g(\bar{v}))) = h_{[5] \mod 2^l}(-1, \bar{v}, h(1 \mod 2^l - 1, \bar{v}, g(\bar{v}))) \).

For the converse, any \( f' = \text{WBRN}(g, h, B) \) is claimed to be definable by \( f(u, \bar{v}) := f(u, \bar{u}, \bar{v}) \), where \( f = \text{WBRN}(g, h, B) \), and \( h(u, x, \bar{v}, z) := h(E(u, x), \bar{v}, z) \), with \( E(u, x) = x \mod 2^u \), being the low-order \( u \) bits of \( x \), assuming \( u \leq |x| \). But, e.g., \( f'(5, \bar{v}) = h(5, \bar{v}, h(1, \bar{v}, g(\bar{v}))) \), while \( f(5, \bar{v}) = f(5, \bar{v}) = F(S_1(0), \bar{v}) = h(1, \bar{v}, h(0, \bar{v}, g(\bar{v})))) = h(1, \bar{v}, h(0, \bar{v}, g(\bar{v})))) \).
The key observation is that the recursion depths of both schemes WBRN and WBRN’ are identical, and hence step-by-step simulations are possible. To see this, we first define the half norm of \( y \), denoted by \( \|y\|_H \), that represents the recursion depth of an WBRN’ instance at \( y \).

\[
\|y\|_H := \min\{k \in \mathbb{N} \mid H^k(y) = 0\}
\]

As \( |(\|y\|)| \) represents the recursion depth of an WBRN instance at \( y \), the above claimed equality on recursion depth then follows by the next lemma.

**Lemma 4.4 (Half Norm).** For any \( y \in \mathbb{N} \), one has

\[
(0) \quad \|y\|_H = |(\|y\|)|
\]

(and so we just write \( |y| \) for \( \|y\|_H \)).

*Proof.* We proceed by course-of-values induction. As \( \|0\|_H = 0 = |(0)| \), consider any \( y > 0 \), say \([y] = 2n+i\), \( i \in \{0, 1\} \). Then \( H(y) = n \) by definition, and we obtain

\[
\|y\|_H = |H(y)|_H + 1 \quad (= |(H(y))| + 1 = |n| + 1 = |2n + i| = |(y)|).
\]

Further facilitating the proof structure, we provide some auxiliary functions.

**Lemma 4.5 (Auxiliary functions).** All of the following functions belong to both CLO and CLO’:

(a) the most significant part, MSP, satisfying \( \text{MSP}(m,n) = \lfloor \frac{m}{2^n} \rfloor = P^n(m) \),

(b) function DROP, satisfying \( \text{DROP}(m,n) = \lfloor \frac{m}{2^{n-1}} \rfloor = P^{n-1}(m) \),

(c) the binary predecessor, \( P \), satisfying \( \text{P}(m) = \lfloor \frac{m}{2} \rfloor \),

(d) the unary conditional, COND, satisfying \( \text{COND}(x,y,z) := \begin{cases} y & \text{if } x = 0 \\ z & \text{else} \end{cases} \),

(e) the binary conditional, CASE, satisfying \( \text{CASE}(x,y,z) = \text{case}(\ x, y, z) \),

(f) and function half, \( H \), satisfying \( \text{H}(m) = \lfloor m/2^{\lceil \log_2 m \rceil/2} \rfloor \).

*Proof.* As for part (a), observe that MSP can be defined by (CRN), since

\[
\text{MSP}(0,n) = 0, \quad \text{MSP}(S_h(m,n)) = \text{SBIT}(S_h(m,n),S_h(m,n))\begin{cases} \text{MSP}(m,n) & \text{if } n > 0 \\ \text{MSP}(m,1) & \text{else} \end{cases}
\]

for \( S_h(m) \neq 0 \). Thus, both parts (b) and (c) follow from (a), since

\[
\text{DROP}(m,n) = \text{MSP}(m,|n|), \quad \text{P}(m) = \text{MSP}(m,1).
\]

As for (d), first define function \( F := \text{BRN}(g,h,b) \) from both CLO and CLO’ functions \( g(y,z) = y, \ h(x,y,z,v) = z, \) and \( b(x,y,z) = 2^{|x|} \cdot y + z \), where \( b \) can be defined by (CRN). Then we already have \( F = \text{COND} \). Thus, as \( |x| = 0 \Leftrightarrow x = 0 \), we can use (WBRN) to define \( \text{COND}(x, y, z) = F(|x|, y, z) \) as a function in CLO. As well, since \( |x| = 0 \Leftrightarrow x = 0 \), we obtain \( \text{COND} = \text{WBRN’}(g,h,b) \in \text{CLO’} \).

Now, part (e) follows from (d), since \( \text{CASE}(x,y,z) = \text{COND}(|\text{BIT}(x,0),y,z) \), and finally, (f) follows from parts (a) – (e), since

\[
\text{H}(m) = \text{CASE}(|m|,\text{DROP}(m,\text{P}(|m|)),\text{DROP}(m,\text{P}(S_1(m)))).
\]

\[\]
Proof. It suffices to consider any \( f := \text{WBRN}(g, h_0, h_1, B) \) in \( \text{CLO} \), assuming \( g, h_0, h_1, B \in \text{CLO}' \). We shall give a direct simulation \( f' \in \text{CLO}' \) of \( f \), that is, \( f(y, a) = f'(y, a) \) for all \( y, a \), where

\[
f'(y, a) := \hat{f}(y, y, a) \quad \text{with} \quad \hat{f} := \text{WBRN}'(\hat{g}, \hat{h}, \hat{B})
\]

for some \( \hat{g}, \hat{h}, \hat{B} \in \text{CLO}' \). Here, the \( y \)-section is defined by

\[
y\{i\} := P^i(|y|).
\]

Referring to (0), suppose that \( |y| = (b_1 |y| - 1 \cdots b_0)_2 \). Then \( y\{i\} = (b_1 |y| - 1 \cdots b_i)_2 \), and \( y\{i\} \mod 2 = b_i \) for \( i < ||y|| \). Therefore, by unfolding the recursions we obtain the following steps in comparison:

\[
f(y, a) = F(|y|, \bar{a}) = h_0(y\{1\}, \bar{a}) \quad \text{steps} \quad f'(y, a) = \hat{h}(\hat{H}^0(y), y, \bar{a}), \quad 1
\]

\[
\vdots \quad \hat{h}(\hat{H}^{i-1}(y), y, \bar{a}), \quad i
\]

\[
\vdots \quad \hat{h}(\hat{H}^{||y||-1}(y), y, \bar{a}), \quad ||y||
\]

\[
\hat{g}(y, \bar{a}) \quad ||y|| + 1
\]

Thus, a stepwise comparison yields the requirement

\[
\hat{h}(\hat{H}^{i-1}(y), y, \bar{a}, v) = h_{y\{i-1\} \mod 2}(y\{i\}, \bar{a}, v) \quad \text{in steps } 1 \leq i \leq ||y||
\]

and step \( ||y|| + 1 \) implies that \( \hat{g} \) can be defined by \( \hat{g}(y, \bar{a}) := g(\bar{a}) \).

By (1) the \( y \)-section implementation in \( \text{CLO}' \) (below) we need this time is

\[
Y(w, y) := P^{||w||-||w||}(|y|) = y[|y| - ||w||].
\]

As (0) implies \( ||H^i(y)|| = ||y|| - i \), we conclude that

\[
Y(H^i(y), y) = y\{i\} \quad \text{for } i \leq ||y||.
\]

Thus, the required function \( \hat{h} \) satisfying (2) can be defined by

\[
\hat{h}(w, y, \bar{a}, v) := h_{Y(y, y)}(Y(H(w), y), \bar{a}, v)
\]

\[
= \text{CASE}(Y(w, y), h_0(Y(H(w), y), \bar{a}, v), h_1(Y(H(w), y), \bar{a}, v)).
\]

In fact, (2) is true of \( \hat{h} \), since (3) implies for \( i \leq ||y|| \):

\[
\hat{h}(\hat{H}^{i-1}(y), y, \bar{a}, v) = h_{Y(\hat{H}^{i-1}(y), y)}(Y(\hat{H}^i(y), y), \bar{a}, v)
\]

\[
= h_{y\{i-1\} \mod 2}(y\{i\}, \bar{a}, v)
\]

For \( \hat{h} \in \text{CLO}' \), it remains to define in \( \text{CLO}' \) function \( Y(w, y) = P^{||w||-||w||}(|y|) \).

First we define by (WBRN') a function \( \ominus' \) satisfying \( ||\ominus'(w, y)|| = ||y|| - ||w|| \).

\[
\ominus'(0, y) := y
\]

\[
\ominus'(w, y) := H(\ominus'(H(w), y)) \quad \text{for } w \neq 0
\]
To see this, observe inductively that for \( w \neq 0 \), \( \| \circ'(w, y) \| = \| H(\circ'(H(w), y)) \| = \| \circ'(H(w), y) \| - 1 = (\| y \| - \| H(w) \| - 1) - 1 = \| y \| - \| w \| \), as \( \| w \| \geq 1 \). Note that the outmost use of \( H \in \text{CLO}' \) in the above definition is not part of the (WBRN') scheme. Now, we conclude the required definition of the \( y \)-section implementation in \( \text{CLO}' \) as follows:

\[
Y(w, y) := \text{MSP}(\| y \|, \circ'(w, y))
\]

To complete the definition of \( \hat{f} \), it still remains to define a bound \( \hat{B} \in \text{CLO}' \), and here we run into a problem. To see this, first observe that one can show:

\[
\| w \| \leq \| y \| \implies \hat{f}(w, y, x) = F(Y(w, y), x) \leq B(Y(w, y), x)
\]

But \( Y(w, y) = \| y \| \) whenever \( \| y \| \geq \| y \| \), hence \( \hat{h}(w, y, \bar{a}, v) = h_{\| y \| \mod 2}(\text{P}(\| y \|), \bar{a}, v) \), which in turn implies that \( \hat{f}(w, y, \bar{a}) \) is obtained by iterating \( \| w \| - (\| y \| - 1) \) times function \( h_{\| y \| \mod 2}(\text{P}(\| y \|), \bar{a}, v) \) on \( f(y, \bar{a}) \). Thus, we cannot guarantee that \( \hat{f} \) can be bounded by a function in \( \text{CLO}' \). To resolve that problem, by use of the functions \( \text{COND}, \circ' \) (both in \( \text{CLO}' \)) and \( \| \cdot \| \), we simply modify \( \hat{h} \) such that it returns 0 whenever \( \| w \| - \| y \| > 0 \). Thus by (4), setting \( \hat{B}(w, y, x) := B(Y(w, y), x) \) will do.

**[CLO' \subseteq \text{CLO}]** It suffices to consider any \( f := \text{WBRN}'(g, h, B) \), assuming inductively \( g, h, B \in \text{CLO} \). Accordingly, the \( y \)-section we need is defined by

\[
y(i) := H^{i+1}(y).
\]

Again, we will give a direct simulation \( f' \in \text{CLO} \) of \( f \) (see above), where

\[
f'(y, \bar{a}) := \hat{f}(y, y, \bar{a}) \text{ with } \hat{f} := \text{WBRN}(\hat{g}, \hat{h}, \hat{B})
\]

for some \( \hat{g}, \hat{h}, \hat{B} \in \text{CLO} \). By unfolding the recursions, we obtain the following steps:

\[
\begin{align*}
\hat{h}(P(|y|), y, \bar{a}, v) &= h_{\| y \| \mod 2}(\text{P}(|y|), y, \bar{a}, v) \text{ steps} \\
\hat{h}(P(|y|), y, \bar{a}, \bar{a}) &= h_{\| y \| \mod 2}(\text{P}(|y|), y, \bar{a}, \bar{a}) \\
\hat{h}(P(|y|), y, \bar{a}, v) &= h_{\| y \| \mod 2}(\text{P}(|y|), y, \bar{a}, v) \\
\hat{h}(P(|y|), y, \bar{a}, \bar{a}) &= h_{\| y \| \mod 2}(\text{P}(|y|), y, \bar{a}, \bar{a}) \\
\hat{h}(P(|y|), y, \bar{a}, v) &= h_{\| y \| \mod 2}(\text{P}(|y|), y, \bar{a}, v) \\
\hat{h}(P(|y|), y, \bar{a}, v) &= h_{\| y \| \mod 2}(\text{P}(|y|), y, \bar{a}, v) \\
\hat{h}(P(|y|), y, \bar{a}, v) &= h_{\| y \| \mod 2}(\text{P}(|y|), y, \bar{a}, v)
\end{align*}
\]

Thus, a stepwise comparison yields the requirement

\[
\hat{h}(P(|y|), y, \bar{a}, v) = h_{\| y \| \mod 2}(y, \bar{a}) \text{ in steps } 1 \leq i \leq \| y \|
\]

and again, step \( \| y \| + 1 \) shows that \( \hat{g} \) can be defined by \( \hat{g}(y, \bar{a}) := g(\bar{a}) \).

By (5), (6) the \( y \)-section implementation in \( \text{CLO} \) we need this time is

\[
Y(w, y) := H^{\| y \| - (\| w \| + 1)}(y) = y(\| y \| - \| w \|)
\]

In fact, since \( \| P(|y|) \| = \| y \| - 1 \), we conclude from (7) that

\[
Y(P(|y|), y) = y(i) \text{ for } i \leq \| y \|.
\]
Thus, we obtain the required function \( \hat{h} \in \text{CLO} \) by setting
\[
\hat{h}(w, y, \vec{a}, v) := h(Y(w, y), \vec{a}, v)
\]
provided that function \( Y \) is definable in \( \text{CLO} \). To see that, using \( H, \text{DROP} \in \text{CLO} \), and \(|w| < |x| \Leftrightarrow |S_1(w)| \leq |x| \Leftrightarrow \text{DROP}(S_1(w), x) = P^{|x|}(S_1(w)) = 0 \), we first define by (BRN) a function \( G \) in \( \text{CLO} \), satisfying \( G(x, y, w) = H^{|x|−|w|}(y) \).

\[
G(0, y, w) := y
\]
\[
G(S_b(x), y, w) := \text{COND}(\text{DROP}(S_1(w), x), H(G(x, y, w)), y)
\]
for \( S_0(x) \neq 0 \). Then define \( \hat{Y}(x, y, w) := G(|x|, y, w) = H^{|x|−|w|}(y) \) by (WBRN), and conclude the \( y \)-section implementation in \( \text{CLO} \) by setting
\[
Y(w, y) := \hat{Y}(y, y, S_1(w)).
\]

To complete the definition of \( \hat{f} \), it remains to define a bound \( \hat{B} \in \text{CLO} \), and again we run into a problem. To see this, first observe that one can show:
\[
|w| \leq ||y|| \implies \hat{f}(w, y, \vec{x}) = f(Y(w, y), \vec{x}) \leq B(Y(w, y), \vec{x})
\]
But \( Y(w, y) = y \) whenever \( |w| \geq ||y|| \), hence \( \hat{h}(w, y, \vec{a}, v) = h(y, \vec{a}, v) \), which in turn implies that \( \hat{f}(w, y, \vec{a}) \) is obtained by iterating \( |w| − (||y|| − 1) \) times function \( h(y, \vec{a}, \cdot) \) on \( f(y, \vec{a}) \). Thus, we cannot guarantee that \( \hat{f} \) can be bounded by a function in \( \text{CLO} \). To resolve this problem, we use the functions \( \text{COND}, |\cdot| \) and \( G' \) below (all of which are in \( \text{CLO} \)) to modify \( \hat{h} \) such that it returns 0 whenever \( |w| − ||y|| > 0 \), and by (8) setting \( \hat{B}(w, y, \vec{x}) := B(Y(w, y), \vec{x}) \) then will do.

As for the required function \( G' \in \text{CLO} \) satisfying \( |G'(y, w)| = |w| − ||y|| \), first observe that the unramified version of \( \oplus \), that is, \( \oplus (u, v) = P^{|u|}(v) \), can be defined by (BRN) from \( \text{CLO} \) functions. Thus, applying (WBRN) to \( \oplus \) yields the \( \text{CLO} \) function \( G'(y, w) = \oplus (|y|, w) \), satisfying \( G'(y, w) = P^{|y|}(w) \). \( \square \)

## 5 Variant CLO\(^{''} \) of CLO

In this section, we consider another variant of Clote’s function algebra that appears in the literature ([1], [2]), the main goal being to give a higher type characterization of NC, building on ideas and techniques presented in [6].

Before defining that variant of \( \text{CLO}' \), first observe that one obtains the same class when replacing scheme (CRN) with the following \( h \)-variant that unlike (CRN) uses a single step function \( (h) \), and where nonzero recursion arguments are not decremented in \( h \).

**Definition 5.1.** A function \( f \) is defined by the \( h \)-variant of \( \text{CRN} \) from functions \( g, h, \) denoted by \( f := \text{CRN'}(y, h) \), if for all \( y, \vec{a}, \)
\[
\begin{align*}
f(0, \vec{a}) &= g(\vec{a}) \\
f(y, \vec{a}) &= S_h(y, \vec{a}) \mod 2(f(P(y), \vec{a})) & \text{for } y \neq 0.
\end{align*}
\]

**Corollary 5.2** (\( h \)-variant). In the context of \( \text{CLO} \) or \( \text{CLO'} \), the \( h \)-variant \((\text{CRN}')\) is equivalent to \((\text{CRN})\).
Proof. Given any \( f = \text{CRN}(g, h_0, h_1) \), we obtain \( f = \text{CRN}'(g, h) \) for

\[
h(w, \vec{a}) := \text{CASE}(w, h_0(P(w), \vec{a}), h_1(P(w), \vec{a})).
\]

Conversely, given any \( f = \text{CRN}'(g, h) \), we have \( f = \text{CRN}(g, h_0, h_1) \) where

\[
h_0(w, \vec{a}) := h(S_0(w), \vec{a})
\]

Unlike the above corollary, the proof of \( \text{CLO}' \subseteq \text{CLO}'' \) does not come so easy, where \( \text{CLO}'' \) results from \( \text{CLO}' \) by replacing scheme \( \text{(CRN)} \) with the \( g \)-variant obtained from \( \text{(CRN)}' \) by setting the base function, \( g \), to the zero function.

Definition 5.3. A function \( f \) is defined by the \( g \)-variant of \( \text{CRN}' \) from function \( h \), denoted by \( f := \text{CRN}''(h) \), if for all \( y, \vec{a}, \)

\[
\begin{align*}
  f(0, \vec{a}) &= 0, \\
  f(y, \vec{a}) &= S_{h(y, \vec{a}) \mod 2}(f(P(y), \vec{a})) \quad \text{for} \ y \neq 0.
\end{align*}
\]

In fact, defining the class \( \text{CLO}'' \) by

\[
\text{CLO}'' := [0, S_0, S_1, \Pi, |, |, \text{BIT}, \#; \text{COMP}, \text{CRN}''', \text{WBRN}']
\]

one ends up with the same class of functions. In [4, p. 77] \( \text{CRN} \) is simulated by the ramified \( g \)-variant of \( \text{CRN} \) (ramified \( \text{CRN}''' \)). As this construction is wrong, we give a proof in the corresponding unramified setting.

Theorem 5.4 (g-variant). \( \text{CLO}' = \text{CLO}'' \)

Proof. As \( \text{CRN}''(h) = \text{CRN}'(0, h) \), the inclusion \( \supseteq \) follows from Corollary 5.2.

\( \text{CLO}' \subseteq \text{CLO}'' \) By Corollary 5.2 it suffices to consider any function \( f := \text{CRN}'(g, h) \), assuming inductively that \( g, h \in \text{CLO}' \). Accordingly, the \( y \)-section is defined by

\[
y[i] := P^i(y)
\]

and by unfolding the recursion, we obtain the following steps:

\[
f(y, \vec{a}) = S_{h(y(0), \vec{a}) \mod 2}(\cdots)
\]

\[
S_{h(y(i-1), \vec{a}) \mod 2}(\cdots)
\]

\[
S_{h(y([y-1], \vec{a}) \mod 2}(g(\vec{a}))\cdots)\cdots
\]

We have the following equation:

\[
f(w; u, \vec{a}) := f'(w; u) := f'(w; u, w)
\]

where \( h'(w; u) := \text{case}(w; u, h'(w; p(; u)), h_1'(w; p(; u))) = C(w; u) = 1 \) and \( h(w; u) := 0 \), and \( f(w; c, u) := s_{\text{case}}(w; u, h'(w; u) \mod c, \text{bit}(w; p(; u), [c-h'(w; u)]) \mod c, \text{bit}(w; P(c), u)) = s_{\text{case}}(v; u, h'(w; u) \mod c, \text{bit}(w; P(c), u)) \) for \( c \neq 0 \). But \( f(1) = 1 \), while e.g. for \( |w| = 3 \) we have \( f'(w; 1) = f(w; u, 1) = s_{\text{case}}(w; u, h'(w; u) \mod c, \text{bit}(w; P(c), u)) = s_{\text{case}}(w; u, h'(w; u) \mod c, \text{bit}(w; P(c), u)) = S_0(S_0(S_1(0))) = 4 \neq 1 \). In general, if \( f(y, \vec{a}) = 2 b_{i-1} \cdots b_0 \), then for sufficiently large \( w, f'(w; \vec{a}) = 2 b_{i-1} \cdots b_0 \).

\[\text{To see this, consider the function } f = \text{CRN}(0, C_1, C_1) \text{ satisfying } f(u; ) = 2^{[u]}. \]

\[\text{It is claimed that for sufficiently large } w, f(w; u) = f'(w; u, u, w) := f(w; u, w, u) \text{, where } h'(w; u) := \text{case}(w; u, h'(w; p(; u)), h_1'(w; p(; u))) = C(w; u) = 1 \text{ and } f(w; 0, u) := 0. \]

\[\text{and } f(w; c, u) := s_{\text{case}}(w; u, h'(w; u) \mod c, \text{bit}(w; p(; u), [c-h'(w; u)]) \mod c, \text{bit}(w; P(c), u)) \text{ for } c \neq 0. \]

\[\text{But } f(1) = 1, \text{ while e.g. for } |w| = 3 \text{ we have } f'(w; 1) = f(w; u, 1) = s_{\text{case}}(w; u, h'(w; u) \mod c, \text{bit}(w; P(c), u)) = S_0(S_0(S_1(0))) = 4 \neq 1. \text{ In general, if } f(y, \vec{a}) = 2 b_{i-1} \cdots b_0 \text{, then for sufficiently large } w, f'(w; \vec{a}) = 2 b_{i-1} \cdots b_0 |w|^{|f(y, \vec{a})|}. \]
To achieve a step-by-step simulation with respect to CRN\(^n(\hat{h})\) for some \(\hat{h}\), we just express \(g(\vec{a})\) as further steps of \(\hat{h}\) that will be performed after the above \(|y|\) steps. The simple idea is that any \(z=(b_{t-1}\ldots b_0)_{2}\) can be written as 
\[
z = S_{b_0}(\ldots(S_{b_{t-1}}(S_0(0))\ldots) \quad \text{for any } k \in \mathbb{N}.
\]
Thus, it is natural to extend the above \(|y|\) steps by further \(\geq |g(\vec{a})|\) steps:
\[
g(\vec{a}) = \text{BIT}(g(\vec{a}),0)(\ldots \text{BIT}(\hat{g}(\vec{a}),|g(\vec{a})|-1)(S_0(0)\ldots)) \quad \text{step } |y| + 1
\]
\[
\vdots
\]
\[
\text{BIT}(\hat{g}(\vec{a}),|g(\vec{a})|-1)(S_0(0)\ldots) \quad \text{step } |y| + |g(\vec{a})| + 1
\]
\[
\vdots
\]
\[
S_0(0)\ldots) \quad \text{step } |y| + |g(\vec{a})| + k
\]
In other words, for the intended bitwise step-by-step simulation we need
\[
\geq |y| + |g(\vec{a})|\text{ steps.}
\]
Of course, exactly \(|y| + |g(\vec{a})|\) steps would suffice, but computing that exact value in CLO\(^n\) is difficult. Instead, we define a function \(f(\hat{w}, w, y, \vec{a}) = CRN^n(\hat{h})(\hat{w}, w, y, \vec{a})\) by recursion on \(\hat{w}\), using \(w\) as a bound on \(|y| + |g(\vec{a})|\), and show that for all \(y, \vec{a},\)
\[
f(\hat{w}, w, y, \vec{a}) = f(W(y, \vec{a}), W(y, \vec{a}), \vec{a})
\]
where \(W\) is any CLO\(^n\) function satisfying \(|W(y, \vec{a})| \geq |y| + |g(\vec{a})|\). For example, setting \(W(y, \vec{a}) := |\text{CASE}(y, S_1(0), S_1(0))|\) will do, since
\[
|W(y, \vec{a})| = 2(|y|+1)|g(\vec{a})| + 1| \geq 2(|y| + |g(\vec{a})|) - 1 = |y| + |g(\vec{a})|.
\]
Now, a bitwise step-by-step simulation w.r.t. (9), with \(w := W(y, \vec{a})\), requires
\[
h(P^i(w), w, y, \vec{a}) = \begin{cases} h(y\{i\}, \vec{a}) & \text{if } i < |y| \\ \text{BIT}(g(\vec{a}), i - |y|) & \text{if } |y| \leq i < |w| \end{cases}
\]
Observe that \(\text{BIT}(g(\vec{a}), i - |y|) = 0\) for \(i \geq |y| + |g(\vec{a})|\). Accordingly, we need a \(y\)-section implementation \(Y(\hat{w}, w, y)\) in CLO\(^n\) satisfying
\[
Y(\hat{w}, w, y) = P[|w| - |\hat{w}|](y).
\]
Then (11) implies that for \(i \leq |w|:\)
\[
P^i(y) = Y(P^i(w), w, y)
\]
\[
i < |y| \iff Y(P^i(w), w, y) > 0
\]
\[
i - |y| = |\text{DROP}(\text{DROP}(w, P^i(w)), y)|
\]
The latter follows from \(|w| - (|w| - i) = i\) for \(i \leq |w|\), and \(|\text{DROP}(m, n)| = |P^{|n|}(m)| = |m| - |n|\), implying \(|\text{DROP}(w, P^i(w))| = i\) for \(i \leq |w|\).

Altogether, as \(P^i(w)\) acts as \(\hat{w}\) in \(f(\hat{w}, w, y, \vec{a})\), the required function \(\hat{h}\) satisfying (10) can be defined in CLO\(^n\) by
\[
\hat{h}(\hat{w}, w, y, \vec{a}, v) := \text{COND}(Y(\hat{w}, w, y), \text{BIT}(g(\vec{a}), |\text{DROP}(\hat{w}, w, y)|), h(Y(\hat{w}, w, y, \vec{a})))
\]
and the \( y \)-section implementation \( Y \) satisfying (11) is definable in \( \text{CLO}'' \), since
\[
Y(\hat{w}, w, y) = p^{\lfloor w \rfloor - \lfloor \hat{w} \rfloor}(y) = \text{DROP}(y, \text{DROP}(w, \hat{w})).
\]
To see that \( \hat{h}, Y \in \text{CLO}'' \), just recall the proof of Lemma 4.5, and observe that the definition of function MSP is, in fact, by CRN'' in \( \text{CLO}'' \). As a consequence, the given definitions of both functions DROP and COND show that they belong to \( \text{CLO}'' \), too. Thus, we obtain \( Y, \hat{h} \in \text{CLO}'' \) as claimed. \( \square \)

6 Embeddings

In this final section, we consider the following ramified function algebras and prove that they all characterize NC, facilitated by \( \text{CLO} = \text{CLO}' = \text{CLO}'' \) established in the last two sections.

\[
\begin{align*}
2\text{CLO} & := \{0, s_0, s_1, \pi, \text{len}, \text{bit, } \#\text{Bel, case, scomp, scrn, slr} \} \\
2\text{NC} & := \{0, s_0, s_1, \pi, \text{len, bit, } \#\text{Bel, case, half, drop, scomp, scrn', slr} \} \\
2\text{NC}' & := \{0, s_0, s_1, \pi, \text{len, bit, sm, } \#\text{AJST, case, half, drop, scomp, scrn', slr} \} \\
2\text{NC}'' & := \{0, s_0, s_1, \pi, \text{len, sm, } \#\text{AJST, } \text{bcase, msp; scomp, scrn', slr} \}
\end{align*}
\]

To explain the new components, a function \( f(y, \bar{x}; \bar{a}) \) is defined by safe logarithmic recursion (the ramified version of (WBRN') defined in Section 4) from functions \( g(\bar{x}; \bar{a}) \) and \( h(u, \bar{x}; \bar{a}, v) \), denoted by \( f = \text{scrn}(g, h) \), if for all \( y, \bar{x}, \bar{a} \),
\[
\begin{align*}
f(0, \bar{x}; \bar{a}) & = g(\bar{x}; \bar{a}) \\
f(y, \bar{x}; \bar{a}) & = h(y, \bar{x}; \bar{a}, f(H(y), \bar{x}; \bar{a})) \quad \text{for } y \neq 0.
\end{align*}
\]
The scheme \( \text{scrn} \) is the ramified form of (CRN'') defined in Section 5, except that the recursion parameter \( y \) in \( f = \text{scrn}(h) \) is in a safe position:
\[
f(\bar{x}; y, \bar{a}) = S_h(\bar{x}; y, \bar{a}) \mod 2(f(\bar{x}; P(y), \bar{a}))
\]
By contrast, scheme (scrn') is just the ramified version of (CRN'') with \( y \) being in normal positions only. Finally, the new initial functions satisfy \( \#\text{Bel}(w; a, b) = 2^{|a| + |b|} \mod 2^{|w|} \), \( \text{sm}(w; a, b) = 2^{|a| + |b|} \mod 2^{|w|} \), and \( \#\text{AJST}(w; a, b) = 2^{|w|^2} \).

These function algebras should be contrasted with those of Bloch [8], namely \( \text{sc(BASE)} := [\text{BASE; scomp, safe DCR}] \) characterizing NC^1, and \( \text{vsc(BASE)} := [\text{BASE; scomp, very safe DCR}] \) characterizing “alternating polylog time.” Here BASE is a large set of initial functions, and the recursion schemes “safe” and “very safe DCR” are similar to the scheme slr. But as scheme scrn is missing in Bloch’s algebras, no characterization of NC is obtained, because scrn is necessary to reach any level NC^k of the NC hierarchy.

Furthermore, 2CLO was defined in [3], and 2NC implicitly in [1]. The idea to split the smash function \( \#\text{Bel} \) into two parts can be found in [2]; we call this algebra \( 2\text{NC}' \). The class \( 2\text{NC}'' \), treated in [28], contains fewer base functions, and uses the following variant of safe concatenation recursion on notation \( f = \text{scrn}''(h) \).

**Definition 6.1.** A function \( f \) is defined by the safe \( g \)-variant of CRN' from function \( h \), denoted by \( f := \text{scrn}''(h) \), if for all \( y, \bar{x}, \bar{a} \),
\[
\begin{align*}
f(0, \bar{x}; \bar{a}) & = 0 \\
f(y, \bar{x}; \bar{a}) & = S_h(\bar{x}; y, \bar{a}) \mod 2(f(P(y), \bar{x}; \bar{a})) \quad \text{for } y \neq 0.
\end{align*}
\]
In contrast to scheme (scrn) in [3], the recursion parameter here appears in a normal position of \( f \) – in consistency with the spirit of ramification –, and unlike the scheme in [2], nonzero recursion parameters, \( y \), must be used in a safe position of \( h \), which is more restrictive.

The development of the above variants of 2CLO was motivated by the wish to achieve a higher type characterization of NC. Such characterizations are useful because programs extracted from proofs of their specifications usually use higher type recursion, which easily exceeds the realm of feasible computation. Therefore, however challenging, one would like to guarantee for a reasonable large class of such extracted programs, usually presented as ramified term systems, that they run in polynomial time or even feasibly highly parallel. While showing correctness of such systems is hard work, completeness is usually obtained by embedding suitable ground type ramified function algebras known to characterize the intended complexity class, e.g. see [13] or [6]. A problem with such higher type systems is that in order to tame higher type recursion, they sometimes lead to very restrictive conditions, such as only allowing the use of “non-size-increasing” functions in recursions and limited usage of “previous functionals” in higher type recursions [14]. Note that the present variants of 2CLO, especially 2NC'' with its restricted scheme (scrn''), were designed exactly for such situations.

Observe that both properties (S2) and (S3) (cf. Section 1) hold for any of the above ramified function algebras. In particular, for every function \( f(x, y) \) in any of the above algebras there exists a poly-max length bound (cf. Section 2).

Inspecting the function algebras characterizing NC considered so far, we obtain the following embeddings.

**Theorem 6.2.** 2CLO \( \subseteq \) 2NC \( \subseteq \) 2NC' \( \subseteq \) 2NC'' \( \subseteq \) CLO'\( \subseteq \) 2CLO

**Proof.** 2CLO \( \subseteq \) 2NC

As the recursion parameter of any scrn(h) is in a safe position, we cannot show directly the required inclusion. However, we can proceed similarly to the proof of 2NC' \( \subseteq \) 2NC''.

2NC \( \subseteq \) 2NC' It suffices to define function \( \#_{\text{Bel}}(w; a, b) \) in 2NC'. As \( \lVert P(2^n) \rVert = x \) and \( p( x) = \text{drop}( x, s_1(0)) \), hence \( p \in 2NC' \), this follows from

\[
\#_{\text{Bel}}(w; a, b) = 2^{\lVert a \rVert \cdot \lVert b \rVert} \mod 2^{\lVert w \rVert^2} = \text{sm}( p( : \text{AJST}(w; )); a, b).
\]

2NC' \( \subseteq \) 2NC'' We must show that the functions bit, half, and drop all are in 2NC'', and that any \( f = \text{scrn'}(h) \) with \( h \in 2NC'' \) is contained in 2NC'', too. Recalling Lemma 4.5, this is easily obtained for those initial functions, since

\[
\begin{align*}
\text{bit}(m, n) &= \lfloor \frac{m}{2^n} \rfloor \mod 2 = \text{case}( m, \text{msp}(m, 0, s_1(0))) \\
\text{drop}(m, n) &= \lfloor \frac{m}{2^n} \rfloor = \text{msp}(m, \text{len}(n)) \\
\text{half}(m) &= \lfloor \frac{m}{2^n} \rfloor = \text{case}( m, \text{drop}(m, \text{len}(m))), \text{drop}(m, \text{len}(s_1(m))))
\end{align*}
\]

where case(\( x, y, z ) = \text{bcase}( x, y, z ) \). For the remaining statement, i.e. \( f \in 2NC'' \) whenever \( f = \text{scrn'}(h) \) with \( h \in 2NC'' \), we run into a problem, since any attempt to define \( f \) directly as scrn''(\( h \)) for some \( h \in 2NC'' \) is tantamount to
turning the normal position of \( h \), to which the recursion \( f \) passes any nonzero recursion parameter, into a safe position of \( \hat{h} \). That cannot work!

To resolve this problem, we will construct for every function \( f(\vec{x}; \vec{a}) \) in \( 2\text{NC}' \) a simulation \( f'(w; \hat{\vec{x}}, \hat{\vec{a}}) \) in \( 2\text{NC}'' \), and a (polynomial) witness \( p_f \) such that

\[
f(\vec{x}; \vec{a}) = f'(w; \hat{\vec{x}}, \hat{\vec{a}}) \text{ whenever } |w| \geq p_f(|\hat{\vec{x}}, \hat{\vec{a}}|).
\]

Building on the above definitions of \( \text{bit}, \text{half}, \text{drop} \) in \( 2\text{NC}'' \), all cases are obvious or standard, except for the case \( f = \text{scrn}'(h) \) with \( h \in 2\text{NC}' \). The I.H. yields a simulation \( h' \in 2\text{NC}'' \) with witness \( p_h \). The witness of \( f \) is then defined by \( p_f(y, \vec{x}, \vec{a}) := p_h(y, \vec{x}, \vec{a}, b_f(y, \vec{x}, \vec{a}))+2y+1 \) for some polynomial length bound \( b_f \).

We'll define a simulation \( f' \in 2\text{NC}'' \) of \( f \) by

\[
f'(w; y, \vec{x}, \vec{a}) := \hat{f}(w; w; y, \vec{x}, \vec{a}) \quad \text{with } \hat{f} := \text{scrn}''(\hat{h})
\]

for some \( \hat{h}(w; \hat{\vec{w}}, y, \vec{x}, \vec{a}) \in 2\text{NC}'' \). Accordingly, the \( y \)-section is defined by

\[
y(i) := P^i(y)
\]

and by unfolding the recursions we obtain the following steps:

\[
f(y, \vec{x}; \vec{a}) = S_{\hat{h}(y(0), y, \vec{x}, \vec{a}) \mod 2}(\ldots = \hat{f}(w; w; y, \vec{x}, \vec{a}) = S_{\hat{h}(w; y, \vec{x}, \vec{a}) \mod 2}(\ldots
\]

Thus, for \( f(y, \vec{x}; \vec{a}) = \hat{f}(w; w; y, \vec{x}, \vec{a}) \) whenever \( |w| \geq p_f(|\hat{y}, \hat{\vec{a}}|) \), a stepwise comparison, together with the I.H. for \( h \), yields the following requirement:

\[
\hat{h}(w; P^i(w), y, \vec{x}, \vec{a}) = \begin{cases} 
  h'(w; y(i), \vec{x}, \vec{a}) & \text{if } i < |y| \\
  0 & \text{else}
\end{cases}
\]

In the presence of \( \text{drop}(m, n) = P^{|m|}(m) \) in \( 2\text{NC}'' \), this time the required \( y \)-section implementation in \( 2\text{NC}'' \) is definable with safe positions only because

\[
Y(; w, \hat{\vec{w}}, y) = P^{|w|+|\hat{w}|}(y) = \text{drop}(; y, \text{drop}(; w, \hat{\vec{w}})).
\]

Indeed, for sufficiently large \( w \), we have for \( i \leq |w| \):

\[
Y(; w, P^i(w), y) = \begin{cases} 
  P^i(y) & \text{if } i < |y| \\
  0 & \text{else}
\end{cases}
\]

Since \( i < |y| \Leftrightarrow Y(; w, P^i(w), y) > 0 \), function \( \hat{h} \) can be defined in \( 2\text{NC}'' \) by

\[
\hat{h}(w; \hat{\vec{w}}, y, \vec{x}, \vec{a}) := \text{cond}(; Y(; w, \hat{\vec{w}}, y), 0, h'(w; Y(; w, \hat{\vec{w}}, y), \vec{x}, \vec{a}))
\]

where \( \text{cond}(; x, y, z) = \text{base}((; x, y, z), z) \).
\[2\text{NC}'' \subseteq \text{CLO}''\] This inclusion is fairly standard, since the functions \(\text{sm}, \text{msp}\) and \(#_{\text{AJST}}\) can be easily defined in \(\text{CLO}''\) (for \(\text{msp}\), cf. Lemma 4.5), and by forgetting ramification we see inductively that every \(f \in 2\text{NC}''\) is definable in \(\text{CLO}''\). In particular, by poly-max bounding and the fact that for every polynomial \(p\) there exists a function \(W_p \in \text{CLO}''\) such that \(p^{|\vec{x}|} \leq W_p(\vec{x})\), every \(f = \text{slr}(g, h) \in 2\text{NC}''\) can be turned into a \(\text{CLO}''\) function \(\text{WBRN}''(g, h, W_p)\).

\[\text{CLO}'' \subseteq 2\text{CLO}\] We will construct for every \(f \in \text{CLO}''\) a simulation \(f' : (w; \vec{x})\) in \(2\text{CLO}\), and a (polynomial) witness \(p_f\) such that

\[f(\vec{x}) = f'(w; \vec{x})\text{ whenever } |w| \geq p_f(|\vec{x}|).\]

If \(f\) is \(0, s_0, s_1, t_i, n, m, |\cdot|\) or \(\text{BIT}\), then we can define \(f'\) directly in \(2\text{CLO}\) using safe composition and projection. If \(f\) is \(#\) then \(#(x, y) = \text{sm}(w; x, y)\) for \(|w| \geq |x| + |y| + 1\), since \(a \mod b = a \Leftrightarrow a < b\).

The cases \((\text{COMP}), (\text{WBRN})\) are fairly standard, leaving the case \(f = \text{CRN}''(h)\) with \(h \in \text{CLO}''\). Here we can proceed as in the case \(\text{scrn}'(h)\) of \(2\text{NC}'' \subseteq 2\text{NC}''\), because in \(2\text{CLO}\) function \(\text{msp}(m, n)\) can be defined by \((\text{scrn})\) from \(\text{bit}(m, n)\) using safe variables only — recall the recursion equations of \(\text{MSP}\) in the proof of Lemma 4.5 —, and hence we obtain as above function \(\text{drop}(m, n)\) in \(2\text{CLO}\).

By Theorems 4.1, 4.3, 5.4, and Theorem 6.2 we have established the following new characterization of \(\text{NC}\).

**Corollary 6.3.** \(\text{NC} = [0, s_0, s_1, \pi, \text{len}, \text{sm}, \#_{\text{AJST}}, \text{bcase}, \text{msp}; \text{scomp}, \text{scrn}''', \text{slr}]\)

SHARE: A Transparent Mechanism for Reliable Broadcast Delivery in CAN

98-15  Mohammad Ali Livani, Jörg Kaiser
Predictable Atomic Multicast in the Controller Area Network (CAN)

99-01  Susanne Boll, Wolfgang Klas, Utz Westermann
A Comparison of Multimedia Document Models Concerning Advanced Requirements

99-02  Thomas Bauer, Peter Dadam
Verteilungsmodelle für Workflow-Management-Systeme - Klassifikation und Simulation

99-03  Uwe Schöning
On the Complexity of Constraint Satisfaction

99-04  Ercument Canver
Model-Checking zur Analyse von Message Sequence Charts über Statecharts

99-05  Johannes Köbler, Wolfgang Lindner, Rainer Schuler
Derandomizing RP if Boolean Circuits are not Learnable

99-06  Utz Westermann, Wolfgang Klas
Architecture of a DataBlade Module for the Integrated Management of Multimedia Assets

99-07  Peter Dadam, Manfred Reichert

99-08  Vikraman Arvind, Johannes Köbler
Graph Isomorphism is Low for ZPP$^\text{NP}$ and other Lowness results

99-09  Thomas Bauer, Peter Dadam
Efficient Distributed Workflow Management Based on Variable Server Assignments

2000-02  Thomas Bauer, Peter Dadam
Variable Serverzuordnungen und komplexe Bearbeiterzuordnungen im Workflow-Management-System ADEPT

2000-03  Gregory Baratoff, Christian Toepfer, Heiko Neumann
Combined space-variant maps for optical flow based navigation

2000-04  Wolfgang Gehring
Ein Rahmenwerk zur Einführung von Leistungspunktssystemen
2000-05  *Susanne Boll, Christian Heinlein, Wolfgang Klas, Jochen Wandel*
Intelligent Prefetching and Buffering for Interactive Streaming of MPEG Videos

2000-06  *Wolfgang Reif, Gerhard Schellhorn, Andreas Thums*
Fehlersuche in Formalen Spezifikationen

2000-07  *Gerhard Schellhorn, Wolfgang Reif (eds.)*

2000-08  *Thomas Bauer, Manfred Reichert, Peter Dadam*
Effiziente Durchführung von Prozessmigrationen in verteilen Workflow-Management-Systemen

2000-09  *Thomas Bauer, Peter Dadam*
Vermeidung von Überlastsituationen durch Replikation von Workflow-Servern in ADEPT

2000-10  *Thomas Bauer, Manfred Reichert, Peter Dadam*
Adaptives und verteiltes Workflow-Management

2000-11  *Christian Heinlein*
Workflow and Process Synchronization with Interaction Expressions and Graphs

2001-01  *Hubert Hug, Rainer Schuler*
DNA-based parallel computation of simple arithmetic

2001-02  *Friedhelm Schwenker, Hans A. Kestler, Günther Palm*
3-D Visual Object Classification with Hierarchical Radial Basis Function Networks

2001-03  *Hans A. Kestler, Friedhelm Schwenker, Günther Palm*
RBF network classification of ECGs as a potential marker for sudden cardiac death

2001-04  *Christian Dietrich, Friedhelm Schwenker, Klaus Riede, Günther Palm*
Classification of Bioacoustic Time Series Utilizing Pulse Detection, Time and Frequency Features and Data Fusion

2002-01  *Stefanie Rinderle, Manfred Reichert, Peter Dadam*
Effiziente Verträglichkeitsprüfung und automatische Migration von Workflow-Instanzen bei der Evolution von Workflow-Schemata

2002-02  *Walter Guttmann*
Deriving an Applicative Heapsort Algorithm

2002-03  *Axel Dold, Friedrich W. von Henke, Vincent Vialard, Wolfgang Goerigk*
A Mechanically Verified Compiling Specification for a Realistic Compiler

2003-01  *Manfred Reichert, Stefanie Rinderle, Peter Dadam*
A Formal Framework for Workflow Type and Instance Changes Under Correctness Checks

2003-02  *Stefanie Rinderle, Manfred Reichert, Peter Dadam*
Supporting Workflow Schema Evolution By Efficient Compliance Checks

2003-03  *Christian Heinlein*
Safely Extending Procedure Types to Allow Nested Procedures as Values
2003-04  Stefanie Rinderle, Manfred Reichert, Peter Dadam
On Dealing With Semantically Conflicting Business Process Changes.

2003-05  Christian Heinlein
Dynamic Class Methods in Java

2003-06  Christian Heinlein
Vertical, Horizontal, and Behavioural Extensibility of Software Systems

2003-07  Christian Heinlein
Safely Extending Procedure Types to Allow Nested Procedures as Values
(Corrected Version)

2003-08  Changleing Liu, Jörg Kaiser
Survey of Mobile Ad Hoc Network Routing Protocols)

2004-01  Thom Frühwirth, Marc Meister (eds.)
First Workshop on Constraint Handling Rules

2004-02  Christian Heinlein
Concept and Implementation of C++, an Extension of C++ to Support User-Defined
Operator Symbols and Control Structures

2004-03  Susanne Biundo, Thom Frühwirth, Günther Palm(eds.)
Poster Proceedings of the 27th Annual German Conference on Artificial Intelligence

2005-01  Armin Wolf, Thom Frühwirth, Marc Meister (eds.)
19th Workshop on (Constraint) Logic Programming
